1. *Choice of case.*—In the matter of the nature of the micro-organism concerned in the disease I have little to say. I think experience shows that the nature of the microbe matters little compared with the nature of the disease process. But even here, though the results in different processes differ widely, I am prepared to give vaccine therapy a trial, and I expect to get some degree of result, whether the process is chronic or acute, localised or general. What *does* matter is that the process shall be one of proved infection. To isolate a micro-organism from some part of a patient's body and to assume that his disease is therefore due to its activities is only the baldest of surmises. This, in the sphere of diagnosis, is the analogue of "phylacogen" in the sphere of treatment. The microbe found may or may not be pathogenic to the patient, and one or other of the vaccines in the mixture used may or may not be specific for the infecting microbe. The diagnostic argument must be much fuller than this; considerations of pathogenicity include the biochemical characters of the microbe, perhaps its effects when injected into animals, tests to determine its reactions with the patient's blood, some quantitative estimate in regard to it, evidence of pathological changes at the site of its discovery, and the constancy with which it is present in the patient and in controls. All of these criteria cannot, of course, often be obtained, but some of them are always forthcoming if care be exercised in the various methods that are at the joint disposal of physician and bacteriologist. Any considerable degree of knowledge as to which micro-organisms most commonly occur as causes of particular infections can, of course, only be gained by experience, and here again the single experience either of bedside or of laboratory is apt to mislead. It is not uncommon to see the most laudable methods wasted and the most reasonable hopes abandoned because the physician does not know that the vaccine he is using is prepared from a microbe which is incapable of producing the lesions of the disease under treatment. Freer discussion with the bacteriologist would perhaps have saved all concerned from disappointment. It is not too much to say that one can sometimes forecast failure for the very reason that the nature of the vaccine used so lacks conviction in its relationship to the disease process.

2. *Isolation of the causal microbe.*—To the proper collection of infected material too much importance cannot be attached. It behoves the physician to acquaint himself thoroughly with the methods of doing this. It is of sufficient importance to do it himself and not to relegate it to the patient or even to the nurse. There is a feeling abroad that, provided certain precautions in the collection of material are given, the actual procedure cannot go wrong. This is a fallacy which leads to many errors and increases difficulties that are quite sufficient already. In the case of the urine in a woman, to name a common example, it is not enough that the specimen should be *obtained* by catheter and allowed to run directly into a sterilised flask; the catheter must be passed with more aseptic precautions than even a trained nurse can be expected to possess. Indeed, a bacteriological training is the only thing that ever teaches any of us properly the ubiquity of micro-organisms, whether we are physicians or surgeons or nurses. The material collected must come from the actual lesion under investigation and not from surrounding parts, where often secondary infections, relatively unimportant, are present. The material collected, again, must be dealt with as promptly as circumstances allow, and the warmer the temperature at the time the more important this is. Many of the failures of vaccine therapy are failures in eliminating contaminations rather than failures in real trials of the method.

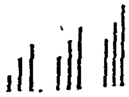
3. *The preparation of the vaccine* scarcely falls within the scope of this discussion, and I doubt if it matters much whether the material is prepared by heat or by autolysis or by the use of antiseptics. Of *sensitised vaccines*, however, I should like to say that I am quite convinced of their superiority to ordinary vaccines in the treatment of acute and of generalised streptococcal infections, having seen them successful when the older method has failed of a result. In the use of *live vaccine* I have had no experience.

4. *The question of dosage and of interval* is very important, although our knowledge is probably at present quite inexact as to both of these factors. We are guided by tradition and personal experience. The range of effective dosage without producing untoward results is probably quite considerable in man, as I was able by experiment to demonstrate is the case in animals. It must be so seeing that different workers give doses of the same vaccine in widely varying numbers and report equally good or equally negative results. Of the various systems of dosage the graduated system seems to have proved the favourite, beginning with a (presumably) subminimal dose and increasing to a dose beyond which it is thought or found that ill effects follow. This is the method I have found most generally useful in chronic infections. (Fig. 1.) In chronic infections that tend to recur (e.g., furunculosis) I prefer to graduate the doses in the reverse order also. (Fig. 2.) In acute infections my experience favours a steppage system of dosage (Fig. 3), giving three doses of increasing size at short intervals, followed by a pause, the second series beginning with the intermediate or final size used at the first series, and so on. I think this serial dosage is also the most useful in employing sensitised vaccine in acute affections. As regards the intervals between the doses, I usually allow the traditional seven to ten days in chronic cases, and 24 to 48 hours in acute cases, with pauses that are determined by the course of the disease and by the apparent effects produced.

FIG. 1.

FIG. 2.

FIG. 3.



5. *Cautions to be observed* include relative rest of the patient and of the affected part for at least 24 hours after the inoculation, and the omission altogether, or the reduction in size, of any dose that is due if the patient suffers undue fatigue, a chill, a menstrual period, undertakes a long journey, or suffers an exacerbation of the condition for which treatment is being given. It is very doubtful if time is ever saved by hurrying; it is

certain that time is often lost by it. I feel convinced that I have several times seen patients rendered hypersensitive to a vaccine by unwise persistence, and requiring lengthy intervals before even small doses could be resumed.

6. *Attention must be paid to all the non-specific points in treatment* just as though the patient were not having vaccine treatment to supplement them. The general condition of the patient is a factor of great importance in getting the best effect from a vaccine; for this reason no therapeutic measure bearing on the state of the blood, nervous system, and general nutrition should be neglected. The response to a vaccine is a specific response, which we are unable by any other known stimulus to produce. All the same, this specific response is more likely to ensue, and ensue more effectively, if the patient's tone is good than if it is bad. Our object is not to see from what depths we can raise the patient by the miracle of a specific stimulus, but rather to supplement those general measures that have already raised him to a certain level, at which he now remains, until the extra leverage of the vaccine completes the process.

VII. *On Certain Problems that Remain.*

I have referred to the fact that certain *limitations* are demonstrable in the use of vaccines as prepared and administered according to our present knowledge. These limitations have already got far beyond anything that the sponsors of the method foresaw at its birth. No doubt we shall hear of several in the course of this discussion.

There are other problems that call for consideration. There is the problem of *recurrences*. A first result of vaccine therapy is often good, may even be brilliant, but cannot be relied upon a second time or, if obtained then, fails at the third trial, even though the method is exactly repeated and the bacteriological diagnosis is carefully revised. What happens here? Is it nothing more than we see in a good many diseases treated on non-specific lines—as in phthisis, for example, where the first chance is a good one, the second doubtful, and the third rarely worth having at all? If so, the problem is not a new one. But the question arises whether we have in some way exhausted the patient's available response to specific stimulation by this particular method.

Then there is the problem of the *generalised infections*, and especially of *malignant endocarditis*, in which, as yet, the results of vaccine therapy, including sensitised vaccines, give us such sparse results. Occasionally in streptococcal septicæmia a few doses of sensitised cocci produce a result which is little short of magical, and now and again a pneumococcal case, similarly treated, gives almost as brilliant a result. But for the most part these cases do not yield; for some reason unknown to us the key does not fit the lock.

There is also the problem of *typhoid fever*, in which, though assistance is undoubtedly rendered in very severe cases by vaccine, the course of an ordinary case is not, according to my experience, shortened or modified.

ROYAL SANITARY INSTITUTE.—The following medical practitioners have been elected members of the institute during the present month: Thomas Adam, M.D. Glasg., Tom William Beazeley, M.B. Birm., and Sydney Taylor Champtaloup, M.B. Edin.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Vaccines from the Standpoint of the Physician.

A MEETING of this section was held on Jan. 27th, Dr. SAMUEL WEST, the President, being in the chair.

Dr. T. J. HORDER read a communication on Vaccines from the Standpoint of the Physician. His paper will be found in full on p 310.

The PRESIDENT, in opening the discussion, said that the term "physician" was meant to include all those who had the opportunity of watching the effects of vaccines from the clinical side He suggested as special points on which emphasis might be laid: (1) the contra-indications; (2) cases where vaccines had been used, had failed, and been abandoned, and the reasons for this; and (3) cases in which definite ill-effects had been produced by them.

Dr. J. CHARLTON BRISCOE commenced with some general remarks, giving reasons for the disappointment which had been experienced by some in results produced by vaccine therapy. He then mentioned three cases—a staphylococcic infection, an asthmatic case with a lesion in the nose, and a case of rheumatoid arthritis, illustrating the points: (1) that a vaccine injection tended to produce local necrosis; (2) the toxic symptoms alone might be relieved; (3) that an infected area ought to be completely removed in order to avoid the risk of a recurrence, even when a vaccine relieved the symptoms. Illustrating the first point, he quoted cases where empyema had followed vaccine injections, and gave a warning against the employment of this treatment in large lesions where drainage had not been effected. He claimed that vaccines diminished the amount and duration of the suppuration which followed the evacuation of pus, and materially assisted the closing of recent sinuses. Illustrating the second point, he remarked upon the striking success which followed the treatment of asthma by the eradication of some septic focus, or by treatment by vaccines grown from the sputum. He instanced three cases in which this treatment was a complete failure, to show that success did not always follow. Following this line of argument, he indicated that bacilluria, when causing symptoms, and rheumatoid arthritis were conditions which were readily relieved by vaccines. He recommended that where possible the infecting focus should be completely removed on account of the liability to relapse when the injections were discontinued. He then related some cases in which recognised treatment had completely failed where vaccines had produced good results. The cases instanced were (1) a staphylococcal cellulitis of the scalp; (2) a bacillus coli infection of the genito-urinary tract; (3) a non-tuberculous caseation of large size in the pelvis; (4) an acute pyrexial polyarthritis (not acute rheumatism); and (5) a bronchorrhœa of 30 years' standing. Finally, he drew the general conclusions: that vaccines were distinctly useful as a therapeutic measure, but should be employed in conjunction with recognised treatment; that all infecting focuses should be removed; that where such was not possible, vaccines might relieve symptoms; and he concluded that he had never seen a case where permanent injury had been produced by this form of treatment.

Dr. H. T. GILLETT said that the results in treatment by vaccines would depend not only on the use of an efficient vaccine, but also on the method of administering the doses. The intensive method of Fornet and Müller had not been successful in two cases in which he tried it, but gradually increasing doses allowing sufficient interval for recovery from any negative phase he had found very satisfactory. About 75 per cent. of his chronic bronchitis cases had responded favourably to an autogenous vaccine; some cases complicated with dyspnœa were very greatly benefited, but some chronic cases were obstinate. He had found that benefit had followed this line of treatment in the following diseases: leucorrhœa, rheumatoid arthritis, septicæmia, pneumonia, and bronchopneumonia; and had almost invariably used autogenous vaccines. On a few occasions he had used sensitised vaccines with good results, but where the patients' powers of response were adequate the ordinary salpingitis. The exceedingly sudden and agonising pain, attended often by vomiting and faintness, with perhaps loss of dark blood per vaginam, served to distinguish ruptured ectopic gestation, while careful bimanual examination would generally disclose a twisted pedunculated fibroid or ovarian cyst. Among diseases common to both sexes were perforated gastric or duodenal ulcer, with epigastric pain of intense and sudden nature, and a history of previous digestive trouble, which also occurred in acute cholecystitis. In typhoid fever with acute onset, a common source of error in which operation had been frequently performed, there was usually a low leucocytic count, the opposite being the case in appendicitis. Acute pancreatitis, strangulation and obstruction of the bowel, inflamed Meckel's diverticulum, renal colic, and malignant growth of the cæcum were among other conditions discussed by Mr. Fletcher, who concluded by emphasising the value of methodical examination and careful consideration of the history of each case.—An interesting discussion followed. Dr. Ryle referred to cases with associated inflammation of appendix and ovary.—Mr. A. H. Buck spoke of the impossibility of diagnosis in many cases even after operation, the exact starting point of inflammation not being traceable.—Mr. Willoughby Furner expressed doubt as to the advisability of a general anæsthetic in cases of appendicitis complicated with pneumonia.—Mr. C. N. Chadborn instanced difficulties in diagnosis from cases of lead colic.—Mr. Morgan discussed cases in which severe abdominal symptoms occurred shortly after labour where there had been slight appendicitis during pregnancy, and Mr. Parry cases following operation for adenoids.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Cancer of the Appendix.—Intestinal Toxæmia.

A meeting of this society was held on Jan. 21st, Mr. James W. B. Hodsdon, Vice-President, being in the chair.

Mr. J. M. Graham read a paper on Cancer of the Appendix, founded on 11 cases of primary cancer, and illustrated with many fine coloured slides. In 1906 Rolleston and Jones had been able to collect details of 37 cases of the disease. Subsequent careful examination of appendices showed the condition to be less rare than was thought. Over 200 cases had now been recorded. The author had found cancer in 6 cases out of a series of 500 appendices removed at operation, or in 1·2 per cent., a slightly higher percentage than Baldauf's 1 per cent. MacCarty and MacGrath in a series of 5000 appendices found cancer in 22 cases, or 0·44 per cent. The tumour was generally small and likely to be mistaken for a concretion embedded in the lumen, or for a diverticulum or a localised inflammatory nodule. In five of his (Mr. Graham's) series of cases it was only on splitting the appendix throughout its length that a tumour could be detected. A most striking fact about cancer of the appendix was its benign nature in most cases. Many names had been applied to the different types of cancer of the appendix, which, however, fell into two main groups: (1) Spheroidal-celled cancers; and (2) cylindrical-celled or colloid cancers. Certain differences could be noted between the two main types: (1) The spheroidal-celled cancer was much commoner; (2) the average age-incidence was 27·2 years; and (3) this type was extremely benign—only one case out of a series of 137 cases gave rise to metastases. As regarded the cylindrical-celled or colloid cancers, (1) these occurred in older patients as a rule, at the average age of 40 years; (2) they had a greater degree of malignancy—metastases occurred in six cases out of a total of 35 in this group; and (3) the average age in the six cases with metastases was 57·8 years. The prognosis must therefore be guarded in cases of cylindrical-celled cancers, especially in middle-aged patients. In the 10 cases of spheroidal-celled cancer described by the author the average age was 24·2 years. In only one case was the patient over 30 years of age. All the specimens but one were obtained at operation. In these cases cancer bore a close relation to appendicitis. In 4 of the cases the appendix was acutely inflamed. In 2 of these cases and in 6 of the others there were chronic lesions at the site of the tumour, suggesting the origin of the cancer at the site of an antecedent lesion. In one case at least the cancer had developed in an otherwise normal appendix, and in this case the tumour had undoubtedly excited the onset of appendicitis. The *site* of the cancer in 6 cases was at or near the tip of the appendix, while in the remaining 4 it was at the middle portion. The *size* of the tumours varied from that of a split shot to a bean. In distribution they occupied the mucous and submucous coats principally. The signs of local malignancy showed themselves in local invasion of the coats, which frequently reached the peritoneal surface and the fat of the mesentery. In 8 of the 10 cases the tumour was of a characteristic golden-yellow colour. In the other 2 cases it was greyish-white in colour. The lumen of the appendix was completely obliterated by the tumour in all but two cases. Microscopically the cells were small, round, or polyhedral and arranged in alveolar masses of varying size, as in scirrhus or encephaloid of the breast. In five of the cases the type corresponded to the scirrhous variety, in three to encephaloid; in two cases whilst mainly scirrhous, areas of tubular adenocarcinoma were present. The evidence in these two cases, which in other respects exactly resembled the rest of the cases in this group, sufficed to demonstrate the origin of these tumours from the secreting *epithelium of the mucosa* and to establish their carcinomatous nature. Vacuoles were fairly common in the cells. The detection of lipoids in the cancer cells explained the yellow colour of the tumours. Examination of frozen sections with the heated stage and polarising microscope showed that the lipoids were of the nature of myelin. This substance was present in the normal suprarenal cortex and in cells of hypernephromata, and explained the golden-yellow colour seen both in the latter and in the spheroidal-celled cancers of the appendix. As regards the relation of cancer of the appendix to obliterative appendicitis, it was probable that cancer of this organ frequently started (1) at the junction of the lumen with a previously obliterated portion; (2) in a partially obliterated lumen; and (3) in the site of a chronic lesion—e.g., ulcer of the mucosa. Certain cases, however, undoubtedly commenced in a healthy mucosa. The origin of a cancer in the narrowed lumen of a partially obliterated appendix would explain the complete obliteration of the lumen by most of the tumours. The changes observed in a series of obliterated appendices showed that (1) traces of the lumen often remained, though to the naked eye obliteration appeared complete; (2) isolated tubules in process of disappearance might be found; and (3) at the junction of obliterated portions the mucosa was often profoundly altered. It was probable that, as in gastric ulcer so in the appendix, chronic lesions might predispose to the origin of cancer. After-history of cases of spheroidal-celled cancer: Six patients reported themselves well at periods of 5, 3, 2½ years and a few months after operation. In no case in which subsequent history was ascertained were there symptoms suggesting recurrence. The eleventh case illustrated tubular adenocarcinoma and was very malignant. This case was that of a male patient aged 48. He had been in ill-health for 15 months suffering from indigestion and occasional vomiting. Pain was felt in the right iliac fossa, and a nodule was present at the umbilicus. At the operation the cæcum was found to be fixed by adhesions and the appendix was very hard, suggesting malignant disease, while secondary nodules were present throughout the peritoneum and in the omentum. The patient died three weeks after the operation, and on examination the specimen was found to be a cancer of the tubular type occupying the centre of the appendix and extending along the mesentery to the cæcum. The appendix beyond the cancer was completely obliterated by fibrous tissue. Conclusions as to the benign nature of the majority of appendix cancer cases, particularly the spheroidal-celled cancers: It might be thought that the spread of the disease to the cæcum would obscure the primary origin of many cases of such appendix cancer. This was not the case, because (1) cancer occurred rarely at the base of the appendix, (2) this type of cancer was rare in the cæcum, and (3) examination of cæcal cancers showed the appendix uninvolved or, if involved, its spread from the cæcum could be observed. Lymphatics drained from the appendix freely into the abdominal glands, and therefore there was no hindrance to the spread of cancer. Cancer of the appendix, especially in spheroidal-celled cases, must be of a naturally benign type, comparable to rodent ulcer, locally invading but rarely giving rise to metastases.—Professor F. M. Caird doubted if cancer of the appendix was as common as those

ıtistics would lead them to believe. He had only met with
o cases, and he invariably cut through every appendix he
noved. The characteristic colour of the tumour would
aw attention to the condition.

Dr. D. CHALMERS WATSON read a paper on Intestinal
ıxæmia, with Special Reference to the Indications for
ıerative Treatment. The paper was illustrated by X ray
ıotographs showing the position of the stomach and the
te of progress of a bismuth meal.—Mr. HODSDON said
at surgeons were greatly divided in opinion as to the
rm of operation. Lane believed that nearly all abdominal
s were due to intestinal stasis, and in severe cases he
cised the cæcum and large intestine. Others contented
emselves by fixing the cæcum if movable, and again,
hers by merely dividing adhesions.—Professor CAIRD had
served that in cases of definite stenosis of the pylorus the
tient almost invariably suffered from vomiting and pro-
unced constipation. After operation such cases improved
eatly and constipation disappeared. Adhesions might be pre-
nt and yet unassociated with symptoms. One met with cases
old peritonitis or ruptured gastric ulcers in which the whole
ils of intestine were matted together, and yet during life
e alimentary canal had been doing its work in normal fashion.
e had operated on a very intense and chronic case of con-
ipation in which the abdominal cavity appeared perfectly
ırmal, and the constipation entirely ceased after the opera-
on. He suggested reviving the ancient plan of raising the
tient's feet more by elevating the lower end of the bed and
ving a nightly dose of castor oil.—Professor WILLIAM
USSELL was not prepared to accept the interpretation
many of the X ray photographs which Dr. Chalmers
'atson had shown, or to accept many of the stomachs
normal, nearly all of them showing a definite degree
proptosis. Ptosis of the transverse colon was exceed-
gly common and could be diagnosed without X ray
amination; it might be extremely marked and yet
ıuse no symptoms whatever. How often and in what
stances were symptoms due to proptosis or delay in the
ıssage of the intestinal contents? That symptoms were
ıe to absorption of intestinal bacterial products as a result
dried fæces had
as certainly not i
ıew altogether the life-history of anaerobic organisms.
'hile he recognised that neurasthenia and rheumatoid
thritis might be greatly benefited by medical treatment,
by no means followed that all such cases were to be
garded as determined by intestinal conditions. As to the
fluence of kinks and bands in an intestine with any
obility, he was a profound sceptic as to fixing the cæcum
to the separation of bands or kinks. He admitted the
enefit of short-circuiting in certain cases, but it would not
lieve all symptoms. He doubted whether the colon was
ıat part of the intestine which ought to be attacked. Often
ıe stomach was at fault, and when short-circuiting was
one in this organ all the other symptoms were frequently
lieved.—Sir JAMES O. AFFLECK asked how, granting all
bout intestinal stasis, did toxæmia arise? Stasis must be quite
ommon, suggesting some defensive action which prevented
ıxæmia. Toxæmia might occur as a result of various
onditions—e.g., a fæcal ulcer causing diffuse abscess of the
ver or a general infection—while bacterial and chemical
ction must account for a good deal of the condition.
ittle had been said about the condition of the canal itself
nd how much it might be involved in the toxæmic condition.
n these cases of intestinal toxæmia medical treatment ought
be persevered in for a very considerable time. When one
as in a difficulty one was too apt to call in the surgeon.—
r. CHARLES W. MACGILLIVRAY had always held that the
hole of the alimentary canal prevented absorption of toxic
ıaterial unless it had become devitalised, as by inflam-
ıation. *Purgatives relieved a loaded bowel but irritated it*
t the same time, and so absorption of toxic products was
llowed.—Dr. H. TORRANCE THOMSON suggested that intes-
inal stasis was a local condition due to a general cause.—
Ir. GEORGE L. CHIENE thought that anchoring the bowel to
ny part of the abdominal wall was wrong. A simple
nastomosis into the transverse colon would give
he advantages without any of the disadvantages.—
Ir. J. W. DOWDEN said that most of these cases occurred
n youngish women, many of whom suffered from a floating
idney on the right side, due to compression of the ribs by
orsets. Short-circuiting in such cases had not in his experience given good results. It might be found that all the symptoms had been due to a small collection of pus in the appendix.—Mr. J. W. STRUTHERS said that an examination after a single bismuth meal could not be relied on. The interpretation of some of Dr. Chalmers Watson's findings was open to question. A proptosed colon might be a perfectly normal one. Adhesions were found frequently in children as well as in adults. These adhesions were so numerous that they must be anatomical conditions. Such adhesions were present in fœtal conditions. In the majority of cases Jackson's membrane, kinks, &c., had no effect on peristalsis and caused no hypertrophy of the bowel behind them. Short-circuiting was often disappointing. An enormous area was left in which putrefaction of the contents might take place and toxic absorption follow.—Mr. E. W. SCOTT CARMICHAEL said that greater experience allowed us to depend less and less on anatomical features as displayed in X ray photographs. The rate of progress of a bismuth meal must vary, not only in different persons, but also in the same person at different times. He thought that the screen gave better information. He thought that tacking down the cæcum or plicating it were operations of doubtful value.—Several other gentlemen took part in the discussion and Dr. CHALMERS WATSON replied.

EDINBURGH OBSTETRICAL SOCIETY.

Early Human Ovum.—Biometric Analysis of Insemination-Labour Curves and Menstrual-Labour Curves in Mammalia.

A MEETING of this society was held on Jan. 14th, Dr. G. F. BARBOUR SIMPSON, senior Vice-President, being in the chair.

Dr. R. W. JOHNSTONE gave a short account of the history of an Early Human Ovum which he had been investigating, and demonstrated the main points of interest in it by a series of colour-photographic lantern slides. The ovum, which was obtained *in situ* from a woman who had died suddenly from fatty heart, corresponded both in size and in the stage of development of the villi to the specimen described by Jung a few years ago, being probably about 16 days old. Unfortunately the specimen had received some damage before being hardened, and this had affected the contents of the blastocyst and rendered their interpretation a matter of some difficulty and dubiety. The woman died suddenly without having missed a menstrual period. The blastocyst contained two large vesicles each consisting of two large cells, and each attached definitely to the mesoderm of the chorion. If these represented the two vesicles of a single embryo, this double attachment was unusual. There was, however, some reason to believe that each vesicle represented a separate embryo, and that the specimen was one of uni-ovular twins. Owing to the damage received by the tissues, it was unfortunately impossible to be certain of this. In connexion with several of the slides Dr. Johnstone discussed shortly the nature and relations of the trophoderm and the mode of formation of the intervillous spaces.—Dr. BARBOUR SIMPSON remarked on the beautiful slides demonstrated by the epidiascope. The case was successfully established as one of early pregnancy, but whether it was a possible twin pregnancy, one could not dogmatise.—Dr. D. BERRY HART remarked on the interest especially of the slides relating to the development of the placenta. He believed the case to be one of undoubted pregnancy, and possibly twin, but he thought the embryonic structures must have died some time before the woman. There was a very good representation of the origin of the placenta, but the real embryonic part had degenerated.—Dr. JAMES YOUNG said that the changes which Dr. Johnstone referred to and so clearly demonstrated had amply convinced him that one had to look to a different explanation of the method of opening out of the maternal blood vessels and the establishment of the blood supply than that set forth in the orthodox t [illegible] demonstrated, it was an extremely [illegible] tended capillaries [illegible] result in pouring [illegible] (Dr. Young) had suggested this some years ago, and Dr. Johnstone's specimen had again clearly demonstrated that possibility.—Dr. J. HAIG FERGUSON, Dr. JAMES RITCHIE, and Dr. W. FORDYCE made remarks, and Dr. JOHNSTONE replied.

Dr. BERRY HART read a paper on a Biometric Analysis of Certain Insemination-Labour Curves and Menstrual-Labour Curves in some Mammalia. He first pointed out that in a previous paper he had stated that certain labour date statistics in cattle (by Spencer) and in ewes (by Tessier) and in the human female (by von Winckel and Reid) when flattened out and grouped in 48 or 96 hourly periods gave a frequency polygon, somewhat skew or humped. It was necessary, however, to flatten out these curves in 24 hourly periods, and then see how they could be treated by Gauss's method of least square. In Spencer's cattle statistics there were 764 animals, and the sum of their days between insemination and labour was 216,451; this divided by 764 gave a mean of 283·3 days. The sum of the square differences between the mean and the actual dates gave 60,649, and the probable error of one observation was found to be 6·012 days. The probable error of the mean was 0·218. Thus are calculated from the date of insemination in cattle a period of 283 days with a probable error of plus or minus 6 days. In Reid's 500 human cases treated in the same way the mean was 278 and the probable error of one observation was 7·748; the probable error of the mean was 0·3466. Thus the date of labour reckoned from the last day of menstruation should be 278 days plus or minus seven days; but the most probable duration was 277·93 or 278·63 days.—Dr. JOHNSTONE said that Professor Arthur Robinson, who had been investigating the subject in ferrets, informed him that if one took a number of ferrets that were inseminated on the same day and then killed them at an early stage of development the embryos were found to be in considerably different stages of development. But when a similar number of ferrets were allowed to go on to full time, then the insemination-labour curve was practically uniform. Apparently from that statement development must go on at a different rate in different embryos, and must in some instances make up for lost time. —Dr. BARBOUR SIMPSON, Dr. HAIG FERGUSON, and Dr. J. LAMOND LACKIE made remarks on the paper, and Dr. BERRY HART replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Cases and Specimens.—Radical Operation for Chronic Osteomyelitis.—Stone and Tumour in the same Kidney.

A MEETING of this section was held on Jan. 9th, Dr. R. D PUREFOY, the President, being in the chair.

Mr. SETON S. PRINGLE showed three examples of operation for disease of the bowel. (1) An excavating ulcer on the lower end in a man aged 65. It was carcinoma of the bowel, and was removed by the combined abdominal and perineal method. (2) A ring stricture of the sigmoid. The case came to him as one of acute obstruction, and the bowel was resected three days later, and the patient was doing well. (3) Sarcoma of the small intestine close to the ileo-cæcal valve. The patient, aged 65, when first seen was thought to have cancer of the cæcum. Radical operation was done and several feet of the ileum removed and an anastomosis made between the ileum and the transverse colon. The patient was now out of hospital and gathering strength.—The PRESIDENT asked how long the symptoms of obstruction continued in the case of cancerous cæcum before there was anything to point to more than increasing constipation. He considered there was much difficulty in trying to decide in those cases as to whether there was really malignant disease. —Mr. W. PEARSON inquired why in the case of acute obstruction a cæcostomy was done, since the contents of the bowel from the cæcum were extremely irritating to the skin. He indicated that he would have preferred to do a colostomy in the transverse colon.—Mr. A. J. McA. BLAYNEY said that in dealing with certain cases of acute obstruction a very distended abdomen was usually met with, and the operator had no means of determining the position of the growth. He suggested that the first thing to do was to make an incision in the middle line. He had experienced no irritation of the skin after cæcostomy, although such might be expected.—Professor W. TAYLOR considered the specimens of very great surgical interest. He thought that in cases of cancer with obstruction in the large bowel the procedure mentioned by Mr. Blayney was the best—i.e., to deal with the obstruction by means of a temporary opening in the cæcum. He agreed that the cæcum was always very much distended in these cases. He could speak from some experience of the very beneficial effects of a cæcostomy preliminary to the major operation.—Mr. W. I. DE C. WHEELER mentioned that five years ago he advocated drainage of the intestine through the cæcum, and he had since no reason to regret this. He could never see any practical objection to cæcostomy, notwithstanding anything said in the text-books.—Mr. PRINGLE, in reply to the President, said that that patient had increasing constipation for a year, and there was obstruction for over ten days. There was no question as to the diagnosis. An aid in such cases was the administration by mouth of a bismuth meal, supplemented by bismuth given through a tube. Another method was the use of the sigmoidoscope. He had found the latter to be quite safe. Regarding cæcostomy, he would always do it when there was a chance of carrying out a radical operation. He had not found that it gave rise to irritation. He recognised the necessity for dealing with as wide a lymphatic area as possible.

Mr. WHEELER showed specimens of Complete Colectomy for mucous colitis, Spindle-celled Sarcoma of Thigh, and Cancer of Stomach, in a patient aged 27.—Mr. C. A. K. BALL mentioned a case of spindle-celled sarcoma in which the patient complained of an abscess in the thigh. This was opened, and the pathological report was that it was a fibroma into which a hæmorrhage had taken place. Six months afterwards a small hard lump occurred in the thigh; this was removed and found to be a spindle-celled sarcoma. It again recurred on two occasions, but the patient recovered, and was well now for over three years.—The PRESIDENT, referring to the case of mucous colitis, inquired what was the prognosis as to the general health of the patient. These were shocking cases to have to deal with, but he thought he could recall some in which the condition disappeared.—Mr. WHEELER replying, said that the patient had no mucous colitis now, and, as far as the bowels were concerned, they were regular. He had been treating the case for two years before doing the colectomy.

Mr. PRINGLE read a communication on Radical Operation for Chronic Osteomyelitis. He first called attention to the unsatisfactory results obtained by the old "gutter" operation. He believed sinuses persisted after this operation because a cavity was left with hard bony walls which could not fall in and assist in obliteration of the space left. He advocated removal of the greater part of the shaft of the bone in such a way that the soft tissues were able to fall in and obliterate any cavity left. In some cases he advocated complete subperiosteal resection of the shaft of the bone.—Mr. BLAYNEY considered this the most important paper read at the section for some time, as it represented a definite step in the treatment of those very troublesome cases. Since he first heard of the procedure he had been carrying out the operation with very satisfactory results.—Mr. WHEELER congratulated Mr. Pringle, and said that he had recently adopted the method in the case of a man suffering from chronic disease of the tibia, and although there was a fracture in the strip of the bone left it gave rise to no trouble afterwards. He was extremely interested in the resection of the bone, as he had been carrying out this in children. He had demonstrated that the periosteum did form bone in children, and the process could be seen in X ray photographs.—Dr. H. DE LISLE CRAWFORD said that he had experience of four cases where the disease spread to the epiphysis, in which he found that the dead bone extended to the end, and that in every case there was a large cavity.—Mr. PEARSON said he thought the periosteum was to be regarded as bone surface. He recalled a case in which there was no necessity for peeling off the periosteum at all, and the entire wound was healed in four weeks.—Mr. PRINGLE, in reply, said he thought that in childhood there was a certain number of osteoblasts lying in the periosteum. There was no doubt that in some few cases the periosteum failed to regenerate bone.

Mr. BALL described a case of Stone and Tumour in the same Kidney. The patient, a man aged 45, had complained for two years of a more or less continuous pain in the region of the right kidney. He had twice passed blood—once about two years ago, once a few days before he came for treatment. The only point noted on examination was a slight but decided tenderness when the right kidney was palpated. The urine contained no blood, pus, albumin, or tubercle bacilli, and beyond a few uric acid crystals nothing abnormal was made out microscopically. An X ray examination showed a small calculus in the pelvis of the kidney. The kidney was therefore exposed by an extraperitoneal incision with a view to removal of the stone, and a tumour was found on the convex border of the kidney, which was therefore removed with the stone *in situ*. The tumour was microscopically a cystadenoma.—The PRESIDENT recalled a case of a large abdominal tumour which he thought was an ovarian cyst, but it proved to be a cystadenoma of the left kidney. Mr. Ball's patient was to be congratulated on having the cyst removed when it was of small size.

Dr. CRAWFORD demonstrated an intestinal drainage trough planned as an effectual means of quickly emptying intestine distended with gas and fæces while preserving the surgeon's gloves and the patient's peritoneum from contamination. The apparatus consists of a metal trough closed at one end by a strong rubber dam, the other leading into a funnel attached to a long piece of rubber tubing. Two long intestinal clips rest in notches cut in the wall of the trough, and the whole is supported on two flat plates of metal. A hole is cut centrally in the dam and the assistant presses a distended loop of bowel against this from the outside, so that a portion of the wall protrudes into the vessel. The operator catches this protrusion with the intestinal clips and secures it by slipping their handles into the notches, thus stretching the rubber and providing a watertight contact. The intestine is then emptied and the cut sutured, using a needle-holder and tying the sutures with a forceps so that there is no risk of infecting the gloves.

MEDICO-LEGAL SOCIETY.—An adjourned discussion of the paper by Dr. Robert Armstrong-Jones upon the urgent need for legislation to permit of the treatment without certification of early cases of insanity, the so-called incipient insanity, took place on Jan. 20th last at 11, Chandos-street, Cavendish-square, W., under the chairmanship of Earl Russell. The paper was published in full in THE LANCET of Jan. 17th, p. 195.—Dr. C. Hubert Bond, one of the Lunacy Commissioners, in opening the discussion, pointed to the need for safeguarding early cases of mental disease against those persons desirous of making money out of their affliction. He referred to the shame felt by the friends of mental cases when it was necessary for them to undergo treatment and the need for privacy which tended at times to overshadow the patient's welfare. He suggested that the term "incipient" would need to be carefully defined to prevent abuse, and it must possibly have application to a time limit from the first onset of symptoms, and to apply to the first attack, or only the early stages of subsequent attacks. He was against an official list of homes, as this might tend to the extension of licensed houses; and he was not officially in favour of what has been described as "single care"—particularly if a definite line of treatment had to be followed. He expressed the sympathy of the Lunacy Commissioners with the desire for greater freedom to treat mental cases in their earlier stages, but with due safeguard against abuse.—Mr. John Carswell described the system in vogue in Scotland for the poor insane, and pointed out the closer connexion between lunacy administration and that of the Poor-law in Scotland than in this country. In Scotland it is also permissible to treat cases of insanity in private homes for a period up to six months without certification, but with notification from the medical attendant that this course was desirable in the interests of the patient.—Mr. James Devon, one of His Majesty's Prison Commissioners for Scotland, also spoke of the necessity for recognising the need for early treatment, and the advantage to the sufferer if this could be done without sending him into the asylum.—Dr. F. S. Toogood described how much was being done in the Lewisham Infirmary under the present law, which admitted a needy case into the Poor-law infirmary and where such a case could be treated for 28 or 31 days under the present lunacy law. He stated that nearly 50 per cent. of all the cases got well within that period and were thus saved from the stigma of the lunacy certificate, which implied a money saving also to the guardians, who were thus freed from the expense connected with certification, removal, and maintenance of the patient during detention in the asylum.—Dr. Henry Rayner quoted his experience in the out-patient department of St. Thomas's Hospital, and was entirely in favour of a change in the law which he himself had been advocating for many years.—Mr. P. T. Blackwell urged that greater freedom should be allowed in treating mental cases in the early stages subject to certain safeguards, and his remarks were supported by Mr. M. I. Finucane.—Dr. O. T. Ewart warmly supported the scheme, and Mr. H. F. Keene, the clerk to the Asylums Committee of the London County Council, related what had already been done by his committee, and he outlined the proposals in respect of treatment in the new Maudsley Hospital.—Sir William J. Collins also summarised the discussion in a clear, eloquent, and practical speech, and Dr. Robert Armstrong-Jones replied.—The following resolution was then formally proposed by Earl Russell and unanimously agreed to:—

> That this meeting of the Medico-Legal Society is of opinion that [illegible] be [illegible] was [illegible]

There was a full attendance of members and visitors.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held in Manchester on Jan. 16th, when Dr. J. H. Willett (Liverpool) was elected President.—Dr. W. E. Fothergill (Manchester) described a case of Fatal Toxæmia of Pregnancy complicated by Vesicular Degeneration of the Chorion. A woman, aged 26, was admitted as an urgency during the seventh month of her third pregnancy. She was delirious. The abdomen was enormously distended by free fluid. The legs and labia were much swelled. The urine contained a large quantity of albumin. The os was closed and there had been no bleeding; it was dilated under ether and the hydatid mole was then diagnosed. The fluid having been removed by an abdominal incision, supravaginal hysterectomy was rapidly performed. The uterus was the size of one eight months pregnant. Its wall was everywhere very thin, but it was not perforated by villi. The whole cavity was filled with vesicles of degenerated chorion. The ovaries were normal. The patient improved for a time, she became rational, took food well, and was free from œdema and hydroperitoneum. Later the toxæmia from which she was suffering on admission regained the upper hand. The legs and labia again swelled and the abdomen once more became filled with fluid. The delirium returned, albumin reappeared in the urine, and the patient died 27 days after the operation. Unfortunately no post-mortem examination was permitted.—Dr. J. Howie Smith (Stockport) showed a Uterus Didelphys, both horns of which had been pregnant at separate times. After giving birth to a macerated premature fœtus the placenta was adherent and the patient died from shock. The uterus was in two completely separate halves which were only joined between the cervices. One-half had been pregnant some years previously and the cervix was much hypertrophied; the other was the one from which the recent child had been delivered.—Dr. H. Leith Murray (Liverpool) read a note on three cases of Pyelitis Developing after Delivery. The cases were atypical (1) in presenting no localising signs or symptoms; (2) in showing a "continuous" fever; (3) in the small amount of pus present in the urine of patients rather seriously ill; and (4) in the onset on the day following delivery. He was inclined to think that this type might contribute to puerperal morbidity more largely than was thought. The condition easily eluded diagnosis if the urine was not centrifuged. Vaccines were of marked service when intelligently administered. The action of urotropin, aided by acid sodium phosphate, should always be controlled by an investigation of the formalin actually formed in the urine; the larger doses of Thomson Walker were strongly recommended.

ROYAL ANTHROPOLOGICAL INSTITUTE.—The annual general meeting of this institution was held on Jan. 20th, Professor A. Keith, the President, being in the chair.—After the reports of the secretary and the treasurer had been read and adopted and the council for 1914 elected, the President gave an address on the Reconstruction of Human Fossil Skulls. He maintained that the ordinary anthropological methods which were employed for the examination and description of complete skulls were not applicable to fragmentary fossil skulls. During the last six years he had endeavoured to discover and perfect methods which might be employed in the reconstruction of skulls from fragments. Recently fragments of a human skull, representative of the pieces of a fossil human skull found at Piltdown, had been submitted to him for reconstruction. A cast of the original skull was kept by those who submitted the fragments to him. There was no apparent trace on the fragments of the middle line along the vault. The reconstructed skull with a cast of the original was submitted to the meeting. The cranial capacity of the original skull was 1395 c.c.; the estimated capacity of the reconstruction was 1415 c.c. As regards width and auricular height the reconstruction and original were in almost complete agreement—the difference being less than 2 mm. In length, however, there was a considerable discrepancy, the reconstruction being 5 mm. longer than the original. The difference was due to the peculiar character of the forehead of the original and also to a mistake as to the probable sex of the skull. The reconstructed skull had been provided with eyebrow ridges of the male type, whereas in the original they were definitely female in character. Tracings of the reconstructed skull were exhibited side by side with similar tracings from the lecturer's reconstruction of the Piltdown skull to show that the problem of reconstruction was the same in each case, and that in all dimensions the cranial cavity of the Piltdown skull was larger than the test skull submitted to him.—At the close of the address Professor G. D. Thane, in moving a vote of thanks to the President, expressed his admiration at the fidelity with which the task of reconstruction had been carried out, and the exact methods which had been employed by the lecturer in his task.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at St. John's Hospital, Leicester-square, on Jan. 20th, Dr. Morgan Dockrell, the President, being in the chair.—Clinical cases were shown by Dr. J. L. Bunch, Dr. W. Griffith, Dr. S. Gooding, the President, and Dr. W. K. Sibley, the last-named of whom opened an adjourned discussion on a paper by Mr. W. Hampson on the Dosage of X Rays.—Dr. Griffith and Dr. Kempster joined in the discussion, and Mr. Hampson replied.

ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of this society was held on Jan. 21st at the Institution of Civil Engineers, Mr. C. J. P. Cave, M.A., the President, being in the chair. The council, in their report, referred to the various branches of work which had been carried on by the society during the past year. These included researches in the upper atmosphere, meteorological lectures, the collection of phenological observations, and the commencement of the preparation of a series of normal values of the climatological elements of the British Isles. The President presented to Mr. W. H. Dines, F.R.S., the Symons Gold Medal for 1914. Mr. Cave, in his presidential address, dealt with the subject of Upper Air Research. He pointed out that research in the upper air may be by means of manned balloon with observer and instrument, or by self-registering instruments sent up in kite, captive balloon, or free balloon. Kites were first used for this purpose by Dr. Wilson, of Glasgow, 1749; and also in Arctic expeditions in 1821 and 1836. The box kite and the use of steel piano wire instead of line enabled greater heights to be obtained. The use of kites was not taken up in England till 1902, when Mr. Dines flew them from a steamer. The President next referred to the various types of instruments used in the research. Rubber balloons are usually used, and as they ascend they tell of the winds above the surface, a special theodolite being used for observing balloons. The International Commission for Scientific Aeronautics directs the studies for upper air research and special days are arranged for international ascents of balloons and kites. The first great result of these researches has been the discovery that the atmosphere is divided into the troposphere, where the air is in constant movement, horizontal and vertical, and the stratosphere, where turbulent motion seems to cease. The stratosphere begins at about 7·5 miles in these latitudes. The method of investigation is new, but it seems as though changes of weather do not begin at the surface of the earth, but are dependent upon movements taking place about 7·5 miles up.

Reviews and Notices of Books.

Studies in Cancer and Allied Subjects.

From the Departments of Zoology, Surgery, Clinical Pathology, and Biological Chemistry. Conducted under the George Crocker Research Fund at Columbia University. Vol. III. New York: Columbia University Press; London: Henry Frowde. 1913. Price $5.00. Pp. 308.

VOLUME III. of the George Crocker Special Research Fund deals with studies from the Departments of Zoology, Surgery, Clinical Pathology, and Biological Chemistry, and includes over 30 papers, some of which, however, are comparatively short and are to be regarded as what the Germans call "Vorarbeiten."

From the Department of Zoology we have first of all a report of the work of the department (1909–11). Next, Gary N. Calkins gives an account of Regeneration and Cell Division in Uronychia and the Effects of Mutilations by Cutting on Paramœcium. Both are substantially reprints from the year 1911. The regeneration problem in uronychia was studied in relation to cell division. It has been generally assumed that a protozoon is able to regenerate at all times with equal facility. This is found not to be the case. This organism when cut takes more than twice the time to divide—three days—than under normal conditions. To explain this it is assumed that substances are formed in the nucleus and transferred to the cytoplasm, where they, or the products of their activity, accumulate until a condition analogous to saturation is reached. Cutting the cell at this period results in the exhaustion of these substances by the process of regeneration, so that cell division is retarded in forms where such division is not already started. Are these hypothetical formative substances of the nature of enzymes? In the cutting experiments on paramœcium it was seen that in addition to profound effects on the power of division of the cells themselves, abnormal growths or "monsters" were formed. In uronychia the power of regeneration is a factor of cell age, increasing as the cell grows older after division, until a maximum power is attained just prior to cell division. In paramœcium the regeneration is very poorly developed, and the nuclear apparatus is more concentrated. From paramœcium to a cancer cell is a far cry, but in general biology a cell is a cell and an organism an organism, regardless of the position in the animal scale, and biological principles are applicable to all. The experiments show that even a minute mutilation of the cell may throw the entire mechanism out of gear, with loss of the power of regulation. In a divided paramœcium, if the nucleus is injured by the knife, neither part lives more than a few hours. Cell division and cell regeneration are entirely independent phenomena.

Then follow short papers on Growth of Tissues under Experimental Conditions, Spontaneous Tumours, Efforts to Bring about Chronic Irritation, Earthworm Experiments, by F. D. Bullock. The same author, along with G. L. Rohdenburg and others, gives an account of Tumour Tissue in Collodion Sacs, Retrograding Tumours, Inoculation with Two Types of Tumours, Effects of Chemical Irritants on the Type of Tissue Resulting from Chronic Irritation, and the Relation of Certain Internal Secretions to Malignant Tumours. There is a short note by P. J. Johnson on Data on Tumour Growth in Relation to Age and Sex of Rodenst.

Mice were inoculated with carcinoma and rats with sarcoma. In some of the communications the number of experiments is very small. The paper on the effects of chemicals after chronic irritation (1911, reprinted) is suggestive. In experiments on rats the most noteworthy results were obtained after injection with xanthin. The investigations, admittedly incomplete as they are at present, suggest that perhaps the end or intermediate products of protein metabolism may affect, not only connective tissue, as xanthin apparently can, but also the epithelial structures. The conclusions drawn from the research on internal secretory glands and tumour growth are to a large extent negative.

From the Department of Surgery there is a reprint (March, 1912) on the Development of the Blastoderm of the Chick *in vitro*, based on the work of Harrison (1907) on the growth *in vitro* of nerve fibres of the frog embryo, of that of Carrel and Burrows, and other transatlantic investigators. From the Department of Clinical Pathology there are three papers by William H. Woglom, entitled "Resistance Produced in Mice against Transplanted Cancer by Auto-inoculation of the Spleen" (published in 1910); "Mice Immunised Subcutaneously are Resistant to the Implantation of Cancer in Internal Organs" (reprinted from THE LANCET of July 8th, 1911, p. 92), and "Contributions to the Individuality of Carcinomata" (published 1911).

From the Biological Department there is first an account of the original programme set forth by William J. Gies. The difficulty of obtaining access to "satisfactory cancerous supplies from human beings and to study cancer patients" led to investigations in directions other than those first proposed. There are five contributions on Methods for the Diagnosis of Cancer, by J. W. Weinstein, Jacob Rosentloom, and others, dealing with, *inter alia*, the tryptophan and glycyltryptophan tests for cancer of the stomach, and the importance of colloidal nitrogen of the urine in the diagnosis of cancer. Then follows an account of the composition of protoplasm and the nature of the structural and dynamic relationships of cell constituents and products by various contributors, and a Study of Lipins—i.e., of lipoids. As to "the glycyltryptophan test of Neubauer and Fischer (1909), it yields positive results in practically all cancer cases, and hardly ever in any others." These tests are obviously of import for the clinician. For details, technique, and sources of errors of the tests, and the data on which the above conclusion is based, we must refer to the original paper. The author states: "I am confident that the tryptophan test out-ranks every other available laboratory means for the diagnosis of cancer of the stomach." The report on the lipins is particularly interesting. These substances play an important part, not only in relation to the enveloping membranes of cells, but also to the cytoplasm itself, of which they form an integral part. Throughout the text the work of the Imperial Cancer Research Fund is freely drawn on and duly acknowledged.

Kurzgefasste Lehre von den Knochenbrüchen.

Von Dr. F. de QUERVAIN, unter Mitarbeit von Dr. TH. CHRISTEN, Dr. H. ISELIN, und Dr. H. ZUPPINGER. I. Teil. Leipzig: F. C. W. Vogel. 1913. Pp. 140. Price, paper, 9 marks; bound, 10 marks.

THE principles of treatment of fractures in this country and in Germany have differed so much in the past that a review of the differences is useful, and probably each country may with advantage learn from the other. The present volume, the first part of a treatise upon fractures by these well-known Swiss surgeons, deals with the principles involved in the production of fractures, in the deformities produced, and in the methods of treatment. It deserves attention, for in it is included a most careful study of theoretical considerations, as well as a very complete account of methods of treatment, more particularly by continuous extension (comparatively new apparently in German countries) and by the use of the semiflexed position of joints.

Continuous extension in the treatment of fractures is old; it dates from the time of Avicenna. But so far as Germany is concerned its development has been to a large extent arrested during the nineteenth century by the attention paid to complete immobilisation by such methods as the application of plaster-of-Paris. The principle of the relief of tension in the muscles by the use of the semiflexed position, together with that of the fixation of the joints above and below a fracture, was enunciated for the first time by Pott. These principles also have been rather neglected, although they deserve a careful study. Perhaps there is a tendency to put a little too much stress upon the production of deformity in fractures by the pull of muscles, and to pass over the displacement due to the direction of the force of the original injury and to the action of gravity. The differentiation of displacements due to these forces, and not liable to recurrence after reduction, from those due to the action of muscles which do tend to recur and therefore require the use of a continuous extension, is an essential preliminary to the enunciation of the principles of treatment of fractures.

Most of the methods of treatment referred to in this volume have at some time been used in this country; some have survived to the present day; others—for example, the use of the semiflexed position—have disappeared; but in any case Professor de Quervain's very careful examination of principles is worthy of study by all those interested in the treatment of fractures.

Epidemic Infantile Paralysis (Heine-Medin Disease).

By Professor PAUL RÖMER. Translated by H. RIDLEY PRENTICE, M.B., B.S. Lond., M.R.C.P. Lond. With 57 illustrations in the text. London: John Bale, Sons, and Danielsson. 1913. Pp. 208. Price 7*s*. 6*d*. net.

Professor Paul Römer's book on epidemic poliomyelitis is already familiar to the neurologist and physician conversant with the German language, and it has justly earned a notable reputation both for the experimental work of its author and for his fine appreciation of the difficulties and problems that the disease still presents from the biological and public health points of view. We compliment Dr. Prentice on his recognition of the wider eminence which the book deserves, and also on his admirably smooth rendering of the original German.

A full and comprehensive description of the various clinical types of the disease as it occurs in man is followed by an excellent chapter on the etiology of the disease, in which the author's experiments on apes are carefully narrated and their significance analysed. The chapter on the pathology and pathogenesis of the disease leaves nothing to be desired for complete and critical investigation. The epidemiology of poliomyelitis, the possibility of immunity and immunisation, experiments with specific antibodies and with drugs, and the question of prophylaxis and State regulation, are other topics handled in the same judicious and discriminating way. There is a bibliography of some 20 pages as well as a good index.

In its English garb we are convinced that Professor Römer's text-book will attain that wider circulation and appreciation which it deserves.

The Mutilated Hand and the Workmen's Compensation Act, 1906, having Special Reference to "Missing" Fingers.

By J. J. SCANLAN, L.R.C.P. & S. Edin., D.P.H. London: The Scientific Press, Limited. 1913. Pp. 98. Price 2*s.* 6*d.* net.

THIS little volume is neither a legal nor a medical text-book, but it will be found a conveniently arranged and instructive guide by members of either the medical or the legal profession who are engaged in compensation cases. Devoted as it is to the study of one important group of accidents coming up for compensation in the county courts, the book contains many useful and practical suggestions for the benefit of medical examiners, advocates, and arbitrators; yet it is not sufficiently bulky to rank as an exhaustive treatise upon a subject the further study of which may be pursued, if necessary, through the pages of other works.

The author has been struck with the abuse that has arisen in claims for damaged hands through the absence of any schedule of fixed amounts for definite injuries. He is inclined to the opinion that sufficient data now exist for the framing of such a schedule in the case of major accidents (such as those involving most of the fingers), subject to every case receiving due consideration upon its surgical, medical, and practical merits. County court judges who have awarded compensation for the loss of fingers will do well to study Mr. Scanlan's accounts of workmen who, having spent their "lump sums," have returned to work at full wages. Some of the points also which the author makes with regard to the objects to be aimed at in assessing and applying compensation of this kind might be studied usefully by members of the legislature anxious to assist the working classes, as well as by judges and those interested as expert witnesses.

Treatment of Internal Diseases.

By Professor NORBERT ORTNER, of the University of Vienna. Edited, with additions, by NATHANIEL BOWDITCH POTTER, M.D., Assistant Professor of Clinical Medicine at Columbia University, New York. Translated by FREDERICK H. BARTLETT, M.D., Instructor of Children's Diseases at Columbia University. Second edition in English, revised and reset from the fifth German edition. London and Philadelphia: J. B. Lippincott Company. Pp. 643. Price 21*s.* net.

THE fifth German edition of this well-known work, which is intended alike for practitioners and students, contains so many alterations from and additions to the previous ones that it has been found necessary to revise completely and reset the translation for the second English edition.

The work is entirely confined to a consideration of the treatment of internal diseases, and physiology and pathology are referred to only to indicate the principles of rational treatment. Throughout the whole volume Professor Ortner emphasises the importance of the mechanical, dietetic, climatic, hydrotherapeutic, and other extra-medicinal methods, giving judicious reasons for those selected. A description follows of these methods with a discussion of the applicability of certain drugs, their respective advantages, disadvantages, and limitations. The author adds useful prescriptions from his own experience and that of others, and so leaves the practitioner who studies this book better prepared to meet etiological indications, and the various contingencies which arise and require symptomatic treatment.

Professor Ortner's remarks are of an essentially practical character, and will be found of special value for reference—that is to say, the book may be consulted as an aid in actual practice. The various diseases are taken in order, commencing with the disorders of the circulatory organs, and detailed descriptions are given of the therapeutical measures which should be adopted. The prescriptions have been altered to conform to the American Pharmacopœia, and the equivalents in the English scale of measures have been added to the metric quantities. In this new edition there are a number of changes in the prescriptions and in the indications and recommendations for modern drugs. The references under climatology, hygiene, and dietetics have been adapted to the needs of the American practitioner and student, but although the work is intended primarily for American readers, practitioners in this country should fully appreciate the value of the information to be gleaned from a study of Professor Ortner's observations. Numerous practical suggestions will be found scattered through the pages of the book.

Treatise on General and Industrial Organic Chemistry.

By Dr. ETTORE MOLINARI. Translated from the second enlarged and revised Italian edition by THOMAS H. POPE, B.Sc., A.C.G.I., F.I.C. With 506 illustrations. London: J. and A. Churchill. 1913. Pp. 770. Price 24*s.* net.

THIS volume is a companion to the "Treatise on General and Industrial Inorganic Chemistry," by the same author, which was reviewed in our columns of Feb. 1st, 1913. The translator of the work on industrial inorganic chemistry was Dr. Ernest Feilmann, and the translator of the present volume is Mr. Thomas H. Pope, of the School of Malting and Brewing in the University of Birmingham. Both translators have adopted much the same methods in rendering the Italian into English, prices in general being given in British currency, while temperatures throughout are given according to the centigrade scale. It would have been an advantage, however, if the translator had included a table of equivalents of English and Italian measures. That the applications of organic chemistry in the industries are as important and numerous as the applications of inorganic chemistry is to some extent illustrated by the fact that both volumes are of much the same size, the work on inorganic industrial chemistry claiming 704 pages and that on organic industrial chemistry 770 pages. The development of organic industrial chemistry has been comparatively recent, and probably its greatest stimulus has been the foundation of the coal-gas industry, which gave rise to an almost illimitable series of valuable products that have found useful application in human affairs. We need only mention the output of hydrocarbons, dyes, disinfectants, medicinal synthetics, and ammonium salts. When, further, we bear in mind that soaps, glycerine, alcohol, sugar, milk products, textiles, tannins, and so forth, count as products of industrial organic chemistry we obtain an idea of the ground traversed in this volume.

It is due to the author to point out that his treatment of the subject matter is cosmopolitan in character, and it would be a mistake to suppose that because the book is the work of an Italian authority the technique described applies only to local methods. This is not the case, for our examination has shown that the author has been careful to give an account of the technological methods adopted in all the manufacturing countries which take an important place in the industrial world. A very valuable feature of the book is the inclusion of the statistics bearing upon production, exportation, and importation in different countries, while the figures given, which refer to the prices of various commodities to date, will also be appreciated by the technological student. There is not much of direct interest to the medical reader, but there is a vast amount of information bearing upon the important position which applied chemistry occupies in industrial affairs. To those attending a course of instruction in chemistry with special reference to industrial applications the book should prove of distinct service.

Les Hystérotomies Vaginales en Obstétrique.

By Dr. ANDRE WILHELM, de la Faculté de Médecine de Paris. Paris: Legrand. 1913. Pp. 244.

VAGINAL hysterotomy is not regarded with great favour in France, and the author of this monograph has done well to collect for the information of his fellow practitioners most of what is known about this operation. As he shows, the procedure permits of the rapid evacuation of the uterus when the cervical canal is closed or incompletely dilated, while the modifications produced by pregnancy in the cervix and lower uterine segment render its execution easy and without danger. In order, however, to render the operation of this character it is necessary to have a sufficiently large opening, and this can be obtained by making a median incision both of the anterior and of the posterior lip of the cervix. The accidents that may occur, such as hæmorrhage, opening of the peritoneum, tears of the uterus, and lesions of the bladder, are not as a rule seen if the technique is good. The ultimate results are generally favourable, and the small number of cases in which pregnancy has subsequently occurred show that the lower uterine segment is not permanently damaged.

Certain conditions are necessary, such as not too large a child, the absence of any pelvic contraction, or of any atresia of the vulva or vagina, and the absence of infection. In these circumstances the operation may be carried out in certain pathological conditions in which an abdominal section is [illegible], while [illegible] of the [illegible]. Some [illegible] en the uterus is to be emptied are eclampsia, retroplacental hæmorrhages, and grave heart disease. The operation should not be practised in cancer of the cervix or in cases of placenta prævia, but it is particularly useful in cases of premature delivery when it is necessary to empty the uterus rapidly. Dr. Wilhelm also considers that this measure might be employed for the rapid delivery of the moribund mother or immediately after her death. Finally, he concludes that the operation is of real value and that it should find a place in the practice of the French obstetrician.

A Clinical Manual of Mental Diseases.

By FRANCIS X. DERCUM, M.D., Ph.D. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 425. Price 13*s.* net.

THIS work, based upon the lectures annually delivered by the author at the Jefferson Medical College, Philadelphia, is designed for both the practising physician and the medical student. With the aid of the descriptions given of the various symptoms presented by patients suffering from mental disorder the student should be able to form a clear idea of the phenomena he is likely to be confronted with in practice and of the treatment appropriate thereto; but whether his conceptions of classification in psychiatry are likely to be clarified, or his confidence in the most up-to-date psychological interpretations of mental morbid phenomena is likely to be increased, is open to question. Indeed, we are inclined to sympathise with the most expert exponents of psychiatry in their endeavours to find a footing in the shifting sands of classification, though even this is a small matter as compared with the welter of opinion through which morbid psychology is passing. "Melancholia-mania," "heboid-paranoid" and "neurasthenic-neuropathic" groups of symptoms are terms over which many may delight to wrangle, but their close definition is difficult and a general consensus as to the possibility of fitting clinical facts to the comprehensive titles suggested for the various syndromes almost impossible to obtain. The borders of dementia præcox, of maniacal depressive insanity, and of paranoia alternately expand and contract with such rapidity that one can only admire the mental agility of those who can intelligently follow the changes which to most are extraordinarily perplexing. We believe, however, that for the student and for the practising physician, except perhaps for those who are of opinion that much knowledge is implicit in a bulky nomenclature, there is no greater boon than the presentation of clear pictures of the symptoms of mental disorder. Such pictures have over and over again been successfully drawn, and in the book before us we have yet another example of descriptions of disease which, one can be confident, tally with everyday experience.

The Diseases of Children.

By HENRY ENOS TULEY, M.D., late Professor of Obstetrics, University of Louisville. Second revised edition. With 106 engravings and 3 coloured plates. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1913. Pp. 684. Price 24*s.* net.

THE second edition of Professor H. E. Tuley's book gives a very complete account of the common diseases of childhood, but he very carefully excludes all reference to the rarer diseases and to those pathological and clinical curiosities which are the breath of life to the professional pædiatrician. As a late professor of obstetrics in the University of Louisville the author might naturally be expected to illustrate his teaching with frequent references to the manifestation of disease in young infants; but as a matter of fact he draws very little from his obstetric experiences, and throughout his writing he leaves the reader under the impression—no doubt quite a wrong one—that he is more familiar with disease as manifested in the adult than with the special characteristics of disease during the ever-changing periods of childhood.

The book, despite its bulk, does not contain a large amount of matter, for its pages are printed in very large, and indeed very excellent, type, with liberal paragraphing, and subheadings are numerous. But we cannot help thinking that the printer (or the author) has made a mistake in heading each page with the title of the chapter and not with that of the particular subsection with which it corresponds. Some of the chapters are very freely subdivided. For instance, that on general diseases includes the following olla podrida of pathological conditions, typhoid fever, rheumatism, diabetes mellitus, tuberculosis, tubercular meningitis, tubercular peritonitis, pellagra, malaria, and syphilis; and each one of these conditions is treated in a separate section, but all are weighted with the comprehensive title, "General Diseases." In the chapter on Contagious Diseases, where again the inclusive title is unfortunately used at the top of each page, the omissions are grave, repeated reference to Koplik's spots does not hide the gaps, and indeed the whole of this chapter might have been taken from a general text-book of medicine published at the end of the last century.

The outstanding feature of Professor Tuley's work is his persistent refusal to acknowledge the rearrangements and reclassifications of disease which the advances of bacteriology have rendered almost imperative. For instance, B. coli and pneumococcic infections are regarded not so much as specific forms of infection vicariously attacking various organs and systems, but rather as the *causæ causantes* of intestinal and pulmonary infections respectively, and in no section of this work can we find any reference to pneumococcic infections of the appendix.

The general impression that we have formed of this work is most disappointing, but there is a redeeming feature in the chapter devoted to the subject of the control and care of milk. As an ex-president of the American Association of Medical Milk Commissions, Dr. Tuley has probably had recent experience in the developments of the milk industry in America, but in any case he has collected a considerable amount of most useful information on this subject and has included it in the chapter on Infant Feeding.

LIBRARY TABLE.

Uganda for a Holiday. By Sir FREDERICK TREVES, Bt., G.C.V.O., &c. Popular edition. London: Smith, Elder, and Co. 1913. Pp. 233. Price 6s. net.—Sir Frederick Treves informs us in his preface that his book is written from "the outlook of the unspecialised traveller, of the man who merely seeks 'somewhere to go to,'" and this may explain the air of boredom which, it seems to us, pervades the book. Sir Frederick Treves touched only the fringe of Uganda and the major part of his book is taken up with a description of his journey to and through British East Africa. His account of the transit from Paris to Marseilles by the P.L.M. express gives the reader the impression of a bad dream, and is, we think, over-coloured, but everyone who has travelled that way will agree with the joy experienced when the traveller wakes up to get his first sight of the Midi. Aden aroused in Sir Frederick Treves sensations from which he found salvation by retiring to the ship's smoking room and turning over "the undisturbing leaves of an illustrated paper a fortnight old." The account given of Mombasa will inspire every reader with a desire to go there, so wonderful are the effects of colour and the romance of the old Arab town. From here starts the Uganda railway, which reaches Port Florence on the Victoria Nyanza after some 580 miles, passing on its way the wonderful Rift Valley. The company is modern in its methods, and from its official publications Sir Frederick Treves has extracted the following interesting items: "Ostriches and ostrich chicks will be carried in brake-vans of goods trains at owner's risk only." "Human ashes are carried in dust-tight boxes at fifth-class goods rates." To be ranked as "fifth-class goods" is even worse than being used to "stop a hole to keep the wind away." Sir Frederick Treves continued his journey by rail (with an interlude of caravan through the Rift Valley) and steamer as far as Ripon Falls, where the Nile leaves the lake. Then he returned and found the journey from the lake to the sea uninteresting, "so uninteresting that the traveller finds more diversion from a six weeks' old London newspaper than he does in a view from the carriage window." The romance of travel would seem to be almost extinct along recognised routes.

War and Women: From Experience in the Balkans and Elsewhere. By Mrs. ST. CLAIR STOBART. London: G. Bell and Sons, Limited. 1913. Pp. 239. Price 3s. 6d. net.—The author presents a clearly written and unvarnished statement of her experiences in the organisation and control of a company of the Women's Convoy Corps, during a ten weeks' sojourn in the Balkans, while giving nursing aid to the Bulgarian forces in the latter part of 1912. The corps had been invited by Queen Eleonora of Bulgaria and by the Red Cross Society and military medical authorities of that State to render assistance in the campaign against Turkey, and as Mrs. Stobart says in her opening chapter, "for the first time in history a company composed exclusively of women has had the experience of going to the front in a campaign, and of improvising and administering in a foreign country a hospital for sick and wounded soldiers." The special feature of the Women's Convoy Corps is that its services are not confined to the nursing of sick and wounded in the wards of hospitals (according to the limitations of the British Red Cross Society), but are available, when required, for sick and wounded in warfare, whatever the conditions may be. The unit numbered 16, including Mrs. Stobart, the commandant and director, two nursing sisters, four other trained nurses, six general duty members, and three women doctors. On arrival at Sofia the detachment was sympathetically received by Queen Eleonora, and then proceeded by rail to Jamboli, and across the Rhodope range and the plains of Thrace by a seven days' bullock wagon trek to Kirk Kilisse, about 40 miles east of Adrianople. Here Mrs. Stobart got ready a hospital with great energy and dispatch, starting it as a going concern within 48 hours of the arrival of the party. This was an extremely creditable piece of work, the finding and taking and cleaning and furnishing of two houses all being accomplished in this time, together with the provision of a certain amount of hospital equipment. Five wounded soldiers were admitted and cared for immediately; four hours later 50 wounded arrived from Chatalja, having undergone a six days' trek in bullock carts without any surgical aid of any kind; their condition may be imagined. Thus the Convoy Corps justified its existence immediately. Mrs. Stobart describes the life from day to day, and gives a lively picture, incidentally disclosing her readiness of resource in emergency, and capacity for making the best of things—even the seven days' wagon journey at a kilometre and a half an hour. The language was a difficulty, not that Bulgarian is hard to learn, but because the people met with were of such various nationalities. The hospital results were extraordinary: of 729 cases only 1 was fatal; 300 of these were serious. Mrs. Stobart attributes the successful results to the healthy condition of the patients, who were of vigorous stock, to the skill and restraint of the doctors in operations, and to the extreme care taken by the sisters in the sterilisation of instruments, &c., in the theatre. We may attribute the success in some part also to the care and supervision as to ventilation and cleanliness of the hospital given by the director herself. Mrs. Stobart has great admiration for the Bulgarian ideal, the ideal of "nationhood," a condition impossible without freedom, and to attain which it was necessary to shake off the Turk. The Turk was defeated because he no longer has an ideal; "the Mohammedan faith is being annihilated by the tide of progress." We are not sure that this can be maintained of Mohammedan races generally; but we are accustomed to call the spirit of such races fanaticism rather than faith in an ideal. The authoress will not allow that war kindles "qualities of heroism,"; it kindles "qualities of brutality." Her disagreement with the Red Cross Society arose from the society's decision to send out only men to nurse the sick and wounded in Bulgaria, which in her opinion signified that "a prominent organisation in Great Britain is still breathing the atmosphere of the times of our great-grandmothers," acting according to the lights of a century ago. The Women's Convoy were, however, on quite friendly terms with the male Red Cross unit at Kirk Kilisse, and the two bodies dined together on Christmas Day. The book is written in a lively style, and the authoress does not disdain to use colloquial expressions which a dozen years hence will need a glossary: "performed on their own," "I was not out for psychological study," "their left hands placed pathetically over their little Marys," are neither more nor less than vulgarisms, out of place in this interesting and well illustrated record of what can be done by women who have pluck and perseverance.

MISCELLANEOUS VOLUMES.

MRS. A. M. USHER, the authoress of *The Management of Children* (with an introduction by FRANCIS B. RUTTER, M.D. Durh., M.R.C.S. Eng. London: J. and A. Churchill. 1913. Pp. 106. Price 1*s.* net), is herself the mother of 12, and consequently has had considerable experience in the management of children, but she admits that she has not had personal experience of all the casualties, mistakes, and diseases which are included in the very considerable and miscellaneous list afforded in these pages. She has acquired knowledge of the rest, however, from reliable hospital nurses and doctors. It is interesting to note that in Mrs. Usher's fully occupied life she has only found time to give others the benefit of her experiences by writing her MS. in pencil while she fed her baby. We cannot help thinking that Mrs. Usher would have been better advised to confine her advice to mothers to such subjects as may be included under the terms "nursing and domestic management." It seems a little beyond the province of a mother—even with the support of experienced nurses and doctors—to take upon herself the responsibility of advising as to treatment of such trivial matters as diarrhœa and constipation, much less on such serious matters as whooping-cough and St. Vitus's dance. And now that the pernicious practice of [illegible]ration by glycerine injections is becoming gradually excluded from our text-books, it seems a pity that Mrs. Usher should revive it, and recommend in addition a still more irrational therapeutic measure—namely, the administration of castor oil. There are, however, a number of useful hints to be learnt from the perusal of this little book, and chiefly with respect to the general management of the nursery.——A useful little book for general instruction is *Home Hygiene* (London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 115. Price 1*s.*), by MRS. HAMILTON WILLIAMS, M.B., B.S. Lond. Mrs. Williams lays down the knowledge of four things as necessary for every girl—viz., how to keep herself in good health, the best and quickest way of doing every sort of work needed in the home, the exact cost of all necessary things that she may obtain the best value for her money, and how to care for little children and when to send for the doctor. The book is divided into four parts in accordance with these four departments of knowledge. It will be seen that the author wisely, as we think, enlarges the scope of the term "hygiene" to cover a wide field. The book is characterised by sound knowledge and common sense all along the lines indicated, and is written in perfectly plain language. It can be highly commended.

Three uncoördinated booklets may be mentioned here. Medical societies are now so numerous and comprehensive that it hardly seems as though there were room for any addition to their number. But should any members of the profession contemplate establishing a new one, some useful hints may be gained from *The Ideals and Organisation of a Medical Society* (London: J. and A. Churchill. 1913. Pp. 51. Price 2*s.* net), by Dr. JAMIESON B. HURRY.——*Some Main Issues* (London: Chapman and Hall, Limited. 1913. Pp. 109. Price 3*s.* 6*d.*) is a collection of essays by Dr. G. WALTER STEEVES on such subjects as Toleration, The Child, Appearances, Letter Writing, Gratitude, The Book Collector, and so forth. They are pleasantly, if not profoundly, written, though every reader will doubtless find [illegible] to disagree with the author.—— [illegible] (London: T. Werner Laurie, [illegible] 6*s.*), is a sort of modern fairy tale about some little boys and girls who have wonderful experiences with mermaids and magic. A 10-year old child, whose opinion of it was invited, said that it was "All right."

JOURNALS AND MAGAZINES.

Surgery, Gynæcology, and Obstetrics. December, 1913.—In this number an account is given of some recent experimental work that has been done by Dr. Nathaniel Allison and Dr. Barney Brooks, of St. Louis, on the subject of the tissue changes which result from the interposition of certain substances between joint surfaces. The first success with the interposition method of treating ankylosed joints appears to have been obtained by Helferich, and he employed a piece of the temporal muscle. This operation was performed for ankylosis of the temporo-maxillary joint, and the case was shown in 1893. Rochet, Hoffa, Nélaton, and others also employed muscle flaps; Gluck used skin flaps; Chlumsky and Hoffa employed non-absorbable material, such as plates of magnesium, silver or tin, or sheets of celluloid or rubber; Hoffa used decalcified bone; Murphy employed flaps of fascia; and Kirschner showed that flaps of fascia which had been detached from their attachments could be transplanted between the bones. Chromicised pig's bladder has been used by Baer. Various other experiments have been performed for the purpose of studying the histological changes in the joint; in many cases a very definite cavity is formed, but opinions differ as to the mode of formation of this cavity and as to the fate of the interposed material. The experiments which have been performed by Dr. Allison and Dr. Brooks were made with the intention of deciding these important points. The knee-joint of the dog was employed and the same operative method was followed in all the cases. The joint surfaces of the patella and the anterior surface of the condyles of the femur were denuded of their cartilage; the substance to be studied was placed between the bones and fixed by fine silk sutures. In all 26 experiments were made. The authors employed the following substances: Cargile membrane, free fascia from the fascia lata, pedunculated flaps of fascia, chromicised pig's bladder, and fascia impregnated with metallic [illegible]. In their paper they give full details of [illegible] obtained, and these may be summarised as [illegible]

ELECTRO-COLLOIDAL THERAPY

COLLOIDAL IODINE IN THE TREATMENT OF TUBERCULOSIS.

Electro-chemical colloidal iodine, discovered by VIEL in 1903, and subsequently tested in the laboratory until 1906, has since then been successfully experimented with in both French and foreign hospitals, the results obtained being published and communicated at the Int. Congress of Tuberculosis (Rome), Pathology (Paris), and the Khedivial Society (Caire).

Iodeol is obtained by dissociating metallic iodine by means of the electric current. The colloidal substance thus obtained is suspended in sterilised olive oil, washed in alcohol and saturated with carburetted hydrogen to prevent the iodine combining with the fatty substances.

The oily suspension ensures durability of the colloidal iodine in a stable form, and renders it possible for the iodine to be kept in suspension in high doses, 0·20 cgrms. to 1 ccm. (isotonic solutions being speedily decomposed owing to the formation of hydriodic acid).

Iodeol is not analogous with Iodo-dextrine, Iodo-Glycogen, Organic compounds of iodine similar to iodide of starch; such physiological colloids do not act as ferments or hydrolysers, and possess neither the antithermic nor the catalytic power of electrically produce colloids (Congress of Pathology, Paris). Electro-chemical colloidal iodine, whilst free from all caustic and toxic properties, possesses in addition to the other properties of colloidal metals in general the bactericidal, antitoxic, and anti-anaphylactic properties of metalloidal iodine. Its non-toxicity enables one to inject very high doses of hyper-active iodine, 16 gr. per diem; in the case of the colloidal metals the dose that can be safely injected does not exceed a few grains.

A large number of experiments within the last six years go to prove that pure electro-chemical colloidal iodine is far more active than the colloidal metals, as it alone acts in severe infections and chronic diseases.

Physical and Physiological Properties.

(A) **Oily suspension;**

(B) Minute, granules hardly visible by the ultra-microscope, as their refractive index *is approximately identical with that of oil*;

(C) Very distinct fluorescence;

(D) **High power of diffusion; it is found present in the urine ten minutes after it has been applied to the skin;**

(E) Precipitated by centrifugalising (at least 16,000 revolutions);

(F) Absolute durability and stability in all climates;

(G) Powerful antithermic, **anti-anaphylactic** and catalyctic action.

A Few References in Medical Literature.

Iodeol is specific for **pneumococcal disease: simple pneumonia, infective pneumonia, broncho-pneumonia, pulmonary congestion** both in man and animals. It acts as a diaphylactic, germicide and lymphagogue, liquefies exudations, modifies the character of the expectoration, relieves cough and dyspnœa, and brings about defervescence within 48 to 72 hours. Mortality barely reaches 3 per cent.

Drs. HERY, BLANC, PHILOUZE (*Therapeutic Society*).
Drs. MIETTE, BRUNET, BOURGEOIS (*Int. Con. Path. Paris*).

Iodeol produces not only those transitory ameliorations in the various forms of **Tuberculosis** that are stated to occur after the use of the most varying forms of treatment, but in most cases after from six to eight weeks' treatment Iodeol will produce a complete change in the condition of the patient. Koch's bacillus disappears from the sputum, which has now become scanty and mucous in character, the physical signs are modified in such a definite manner that, when added to the fact that the weight has increased and the strength of the patient improved, &c., the impression remains that the lesions are fairly on the road to cicatrisation.

Drs. NIMIER, LAUMONIER, ORJUBEN
(*Int. Cong. Tuberc., Rome, April, 1912*).

COLLOIDAL IODINE IN THE TREATMENT OF GONORRHŒA.

(Extract from the Gazette des Hôpitaux.)

In addition to the properties common to the electric colloids the oily suspension of electro-chemical colloidal iodine possesses the bactericidal properties of metalloidal iodine. In the following we give some of the results of our experiments in gonococcal infections: gonorrhœa, &c.

The metallic salts at present utilised in the treatment of gonorrhœa (zinc, mercury) in the main act as **caustic agents,** and are only **slightly bactericidal.**

Colloidal Iodine, on the other hand, acts owing to its diffusibility, it impregnates the mucous membranes and muscular tissues with iodine; on coming into contact with the latter, micro-organisms can no longer live, and it can be demonstrated that **gonococci and staphylococci disappear in a few hours.**

Owing to its being non-caustic Colloidal Iodine cannot cause stricture, nor is any harm likely to be caused even if a few drops accidentally reach the bladder; **no inconvenience is caused.**

The technique is simple and can be carried out by anyone. The injection is given either with a glass Pravaz syringe of 2 ccm. capacity, or with a syringe having a Janet nozzle. The fluid is injected well back into the urethra and there retained for a few minutes; **there being no pain** the patient can retain the fluid as long as he chooses.

We here give two cases:

"M. B. (Paris), 26 years of age.—Gonorrhœal discharge for three days, discharge abundant, pain considerable; 2 ccm. of Colloidal Iodine injected on the first day. The pain is diminished and the discharge decreased; on the following day a further injection of 2 ccm. is given, microscopical examination of a specimen shows that the gonococci have disappeared."

"M. D., 30 years of age.—Gonorrhœa for 15 days with abundant discharge. An injection of 2 ccm. of *Colloidal* Iodine was given at 10 A.M. By the afternoon the pain had ceased and the discharge had been stopped. At 8 P.M. another injection of 2 ccm. was given. On the next day the discharge had completely stopped, and the patient, considering himself cured, returned to his ordinary mode of life. Bacteriological examination, no gonococci."

We deem it our duty to draw attention to this action of Colloidal Iodine, since it brings about a rapid and certain cure in gonorrhœa and causes a disappearance of the gonococci, without in any way interfering with the integrity of the organs.

Drs. MIETTE and TRUFFIER.

THE LANCET.

LONDON: SATURDAY, JANUARY 31, 1914.

Coroners' Inquests on Deaths under Anæsthetics.

Is it desirable in the interests of the public that inquests should be held in all cases of death under an anæsthetic? The vexed question has been recently reopened. The coroner for Southwark, Dr. F. J. WALDO, who has contended before that inquests in these cases are beneficial in so far that they afford an opportunity, if not for censure, at least for admonition, pointed out on a recent occasion that owing to representations made from his court the system of giving anæsthetics in a large general hospital had been carefully overhauled, with the result that the number of specially selected men serving as anæsthetists had been increased, while the fatalities from anæsthetics in the institution had become fewer. Dr. WALDO is a very wise and experienced official, and is not alone in the belief that the holding of inquests in every case of death during the administration of an anæsthetic is advantageous, since the publicity engenders greater caution, while raising the standard of excellence achieved by the persons who administer anæsthetics. Some go further than this. It has, indeed, been suggested that all patients who die during or as the result of operations in public institutions should have their deaths made the subject of a coroner's inquisition. This suggestion we do not discuss; it appears to be made in direct opposition to public interest, which demands that the officers of our hospitals should do their best without fear. The matter presents grave difficulties and complex problems enough when we are considering only the question of fatalities during the use of anæsthetics.

Mr. T. I. BENNETT, an anæsthetist to Guy's Hospital, at the recent inquest held by Dr. WALDO, while admitting that the verdicts of coroners' juries had subserved a useful purpose, accentuated the view that there is another side to the matter. The anæsthetist subpœnaed to give evidence, he contended, suffers in many ways. The coroner is not an anæsthetist, and although among coroners there are many medical men who possess great knowledge blended with considerable forensic acumen, yet it is impossible for any coroner, unless aided by expert help, to differentiate between deaths due solely to the use of an anæsthetic and those resulting from the depressed vitality of the patient, or the unavoidable collapse incident to surgical or accidental trauma. The obvious factor is the anæsthetic, which is known to be capable of producing death; the intangible is that a patient may be in a practically moribund state brought about by surgical procedure; its very intangibility prevents such a factor from receiving the attention for which it cries aloud to the expert. Yet the anæsthetist in a coroner's court may not belittle the effect of his share in the terrible eventuality, nor emphasise the dangers that must have attended his surgical colleague's manipulations in any particular case. To the heedless man it is axiomatic that some of those who have to submit to the ministrations of the skilled surgeon may die; their death is due, he believes, to causes which Providence alone can control. But death as a result of anæsthesia usually suggests to the public that something went wrong. No one was to blame, but why did it occur? Mr. BENNETT observed very justly that no note is taken of the countless thousands of successful anæsthesias; the one death looms large in the forefront of the coroner's court. This is the natural result of the accepted views about the terrors of surgical operations and the ease of producing anæsthesia. The coroner's inquiry, no doubt, was originally intended to ascertain whether a person died as a result of crime, of accident, or of natural causes; it now attempts to appraise the merits of the technical side of the anæsthesia, and the anæsthetist is placed at a disadvantage in dealing with "twelve good men and true" who incidentally are guiltless of special knowledge, so that he cannot go into technical details. He is practically being placed on trial at every one of these inquests for an offence, and his evidence is not infrequently met by that of a pathologist who knows nothing about the clinical aspects of the case—aspects which are essential to forming an accurate judgment. This would seem to indicate that whatever advantages a coroner's inquiry may have, and we submit all medical men will recognise that such advantages exist under favourable conditions, yet the inquiry is in many cases of little utility, and is useless from the point of view of scientific investigation.

In many serious cases the anæsthetist must be placed in a difficult position. His knowledge may convince him that the patient's condition is so grave as to make the attempt at inducing anæsthesia almost a forlorn hope, and yet he cannot allow the patient to sacrifice one scintilla of his chances. He may do his best, but no man can gauge what resisting power remains to the patient, and so death may follow. Strive as he may, a certain stigma rests on the anæsthetist, especially if death occurs before operative measures have commenced. Besides such considerations, another weighty aspect of the question remains. All the narratives of "deaths under anæsthetics" which are detailed at coroners' courts find their way into the daily press. The reports are compressed into a few lines, and almost invariably the death appears as if it had been caused by the anæsthetic. [illegible] paper paragraphs recur day after day, those whose lives depend upon a successful operation being undertaken, become obsessed with an unreasoning dread of taking an anæsthetic. This dread is doubly dangerous; on the one hand, it may lead the patient to refuse treatment and betake himself to one of the many quacks who batten on such folk; or, on the other, it may throw him into a state of panic, thus engendering the worst state possible for successful and safe anæsthesia. When, then, the whole matter is looked at dispassionately we see that the advantages and disadvantages of publicity much counterbalance each other, and, further, that some changes in the law are necessary.

Hospital Statistics and the Science of Medicine.

THE numbers of patients that come under observation at a large hospital should form a basis upon which statistics of value to medical science might be founded. Experience, however, has taught that unless careful and skilled precautions are taken fallacies are so likely to arise that the final conclusions are not to be relied upon. The reasons for this are sufficiently obvious. Amongst the most prominent are the class of patients from whom the necessary information with regard to family and personal histories has to be obtained, the difficulty of always procuring a sufficient number of instances of the disease under investigation, and the manner in which the records of the cases are collected. These points were frequently apparent in the discussion on the Influence of Heredity in Disease which took place at the Royal Society of Medicine in 1908. Professor KARL PEARSON then remarked that it was extremely difficult in a London hospital to obtain material for accurate deductions, and all the staffs of large metropolitan hospitals will corroborate this. It is not that the patients wilfully make wrong statements as regards their family history, but often they are in ignorance of the true cause of the deaths of their parents and relatives, and often they have grave defects of memory. Professor PEARSON expressed the opinion that the memory of the peasant in the north of England and in Scotland is far better, and the pride of family is far more intense than in the average Londoner of the general hospital population. A sufficient number of cases is very necessary for statistical purposes, as it is evident that nothing can be more fallacious than forming opinions on a review of a small number of cases, and yet we must feel that a good many cases are recorded in an untrustworthy manner. The clinical records of our hospitals leave much to be desired, but the defects are difficult to remedy. In many of the hospitals the notes are made by students or the resident officers, and these are supervised by the registrars and the members of the visiting staff. The value of the notes, especially when taken by the students, largely depends upon the manner in which they are corrected and amended by the physicians and surgeons, and even then, although perhaps useful from a purely clinical point of view, for the purposes of obtaining statistics for any investigation they may be of little worth. Omissions which are of little consequence in one direction may have great significance in the other.

One of the most frequent uses for which statistics are prepared is to demonstrate the results of treatment. The difficulties here met with are well shown in the attempts that have been made to arrive at conclusions as to the therapeutics of pulmonary tuberculosis in hospital and sanatorium practice. In the first place, a definite diagnosis must be arrived at, and much difference of opinion, which we need not enter into here, exists in regard to the methods of diagnosis. Next, too much stress has been laid on the results obtained in a small number of cases. In order that any true criterion may be formed many hundreds of cases must be observed. Again, in hospital practice, a further and greater difficulty is experienced—namely, that after leaving the institution a large number of patients are lost sight of, so that their future progress cannot be recorded. Every effort may be made to keep in touch with discharged patients, but the number of those who do not report themselves, or cannot be heard of, is so big as greatly to invalidate the result of any investigation. In such inquiries, too, it is difficult to eliminate the personal equation. Taking all these things into consideration we see that in compiling medical statistics the services of one skilled in the science should be obtained whenever possible. This was suggested in an interesting article in *The Hospital* recently, in which it was proposed that a bureau might be formed under the supervision of a statistical committee nominated by the authorities of the different hospitals concerned. In this way certainly an orderly manner of keeping our hospital records would be much expedited.

In some other branches of medical service, however, hospital statistics may be of true value if ordinary care is taken. The results obtained in the treatment of the infectious fevers at the special hospitals are not so open to the objections we have mentioned, and the after progress of these cases may be more easily followed by the help of the health authorities. So, too, on a smaller scale in the general hospitals, the results of operations may be compared and checked. Also the frequency of complications and their results in various diseases form a subject for statistical investigation less open to fallacy. The main difficulty in instances of this nature would be to obtain a sufficient number of cases. The suggestion of a central bureau for the collection of statistics was made in a discussion at the Royal College of Physicians of London in reference to tuberculosis, and an extension of this idea might perhaps be made in other pathological directions. A director at the bureau whose formation has been suggested, with suitable assistants trained in medicine and statistics, would be able to control investigations, laying down the manner in which the necessary information must be collected. Some of the difficulties we have mentioned might thus be lessened. And although the collection and collation of medical statistics can never be other than a difficult matter, results could surely be obtained which, being the consequence of careful study and inquiry, would aid still further the advance of the science of medicine.

◆

The Protection of India from Yellow Fever.

IT is little more than ten years since Sir PATRICK MANSON first sounded a warning note as to the possible danger of extension of yellow fever to Indian and other Asiatic ports after the opening of the new ship canal through the Isthmus of Panama and the establishment of new trade routes from Central and South America across the Pacific. The reality of this danger has been admitted more recently by many other experts. Although up to the present time no cases of yellow fever have been reported in India, it is now generally recognised that at many Indian ports all the necessary conditions exist for favouring the spread of the malady, and that if the infection unfortunately were once introduced by ships arriving from an infected place the disease would rapidly become epidemic and cause serious loss of life. The tiger mosquito, Stegomyia fasciata, the insect transmitter of the disease to man, is present in great abundance at many Indian ports. The same remark applies to a number of seaports in other parts of Asia and in Oceania, including some in Southern Japan and China, the Malay Peninsula, the Straits Settlements, the Dutch East Indies, the Philippine Islands, Honolulu, Fiji, and Eastern Australia, especially Queensland.

We have discussed already in these columns[1] some of the possible results as regards the spread of exotic disease, including yellow fever, that might follow the opening of the Panama Canal, referring to the development of trade with backward republics in Central and South America where yellow fever is endemic, particularly the State of Ecuador and its chief port Guayaquil, known familiarly as "the pest hole of the Pacific." Quite recently Major S. P. JAMES, I.M.S., who had been instructed by the Indian Government to inquire fully into the subject, has visited Panama and travelled along the new routes which will be used when the Isthmian Canal is opened, calling at the various ports between Panama and India to ascertain their condition and preparedness for dealing with imported yellow fever infection. He has now summarised his facts and conclusions in an interesting paper published in the *Indian Journal of Medical Research* (Vol. I., No. 2). Major JAMES has looked at the subject in various aspects, not forgetting the Imperial point of view, and has dealt not only with Indian ports, but with others, such as Hong-Kong and Singapore. He believes the danger of the introduction of yellow fever to be a real one as regards Hong-Kong, but that the spread of the disease to Indian ports *viâ* Singapore is only likely to occur as a secondary event, subsequent to and dependent upon infection of ports in Japan, China, Farther India, or Australia. He is disposed to think as a result of his inquiries that it is by no means certain that the opening of the Panama Canal will increase the risks of the spread of yellow fever to the extent that has been anticipated. Major JAMES may therefore be regarded as taking a hopeful view of the situation, especially as the work already done by the Isthmian Canal Commission has eradicated yellow fever from the Canal Zone. So long as the present enlightened policy is followed and practical measures are carried out in that region there is, we agree, not the slightest danger that yellow fever will again become endemic in it. There is therefore practically no risk of ships becoming infected while passing through the new water-way, or of their conveying the disease across the Pacific to Indian or other Asiatic ports. But in other areas of Central and South America where yellow fever is still endemic, it cannot be said that the same comprehensive measures to grapple with the disease and its insect host have been applied; so that should such republics develop larger trade relations by shipping with ports in the Pacific or in Asia the danger would necessarily increase. In suggesting means for securing the safety of India, and incidentally of other British ports in Asia and Oceania, Major JAMES advises that at Hong-Kong and other places immediate steps should be taken to destroy the stegomyia mosquitoes and their breeding-places, and that the arrangements in force for dealing with infected ships should be improved and extended, so that any ship-borne case may be safely and promptly dealt with. He particularly urges the Imperial Government to appoint three special medical officers possessing the necessary qualifications and experience, one of whom should be stationed in the Panama Canal Zone, one at Hong-Kong, and one at Singapore. Their primary duty would be to act as intelligence officers, to watch for the occurrence of yellow fever (and perhaps other exotic disease), to report such cases and the measures taken to deal with them, and to keep themselves thoroughly acquainted with the local and trans-Pacific shipping and the routes followed. These officers would be in touch with the local consular and quarantine officials, and would furnish to headquarters at first hand full information as to the progress and diffusion of yellow fever (and other exotic disease) in that part of the world. It is also suggested that a central intelligence bureau should be established through which India and all other British colonies and dependencies would receive immediate information concerning the incidence of the disease: Major JAMES suggests that, if the Imperial Government cannot see their way to make such appointments at once, the Indian Government should itself select three officers of the Indian Medical Service and station them respectively at Panama, Hong-Kong, and Singapore at its own expense.

---

[1] THE LANCET, Feb. 10th, 1912.

We think that the appointment of these intelligence officers would be a practical measure of great importance to our Indian community. Investigations on a systematic and definite scheme should now be undertaken as to the distribution of stegomyia fasciata in Asiatic ports, and efforts should be made to discover if any other species of stegomyia, and especially S. scutellaris, so common in Asia and Oceania, can act as transmitters of the yellow fever infection to man. Renewed researches likewise should be made to settle, if possible, the outstanding problems relating to the etiology and prevention of the disease. As regards the practicability of reducing the numbers of the stegomyia mosquitoes in Indian ports, the key of the problem appears to be the provision of piped water-supplies delivered under pressure to the houses so as to obviate the storage of water in cisterns or temporary receptacles which are at once used as breeding-places by the stegomyiæ. Some ports—Madras, for instance—have a piped supply, but pressure is only put on for a short time daily, consequently in some parts of the city water has to be stored in vessels of various kinds for the next 24 hours. At Bombay the supply is intermittent, and the inhabitants have therefore to store water for domestic use. Lastly, the keeping of yards and compounds free from rubbish, such as discarded crockery, tins, bottles, and the like, is essential. Such measures as improvement of water-supplies, or keeping of backyards clean and free from rubbish and obstructions, are not only of value in the prevention of yellow fever, but, as has been pointed out over and over again in these columns, in many other ways they act beneficially upon the public health, so that money expended for these purposes is to be regarded as a good investment for any community. We hope that the authorities concerned will give their serious attention, if they have not already done so, to the advice given to them by so competent an expert as Major JAMES.

MANCHESTER ROYAL INFIRMARY.—Mr. Walter G. Carnt, the general superintendent and secretary of the Manchester Royal Infirmary, points out that the support accorded to the infirmary by out-districts is nothing like commensurate with the benefits received. He says that the annual deficiency in the infirmary's income is brought about by the lack of support in the area surrounding Manchester and Salford, for in 1912 the patients from the outside districts cost the infirmary £14,000, whilst only £2000 were received in subscriptions from the districts referred to. From one outlying district where patients cost the infirmary £260 only 16 guineas were received in subscriptions.

Annotations.

"Ne quid nimis."

ENGLISH VITAL STATISTICS FOR 1913.

FOR the information of those of our readers who are specially interested in public health matters we printed last week (p. 263) a table which has been issued provisionally by the General Register Office within a few days of the close of the year to which it relates. The mortality at all ages is now authoritatively declared for each of the main statistical divisions of England, as recently determined by the Registrar-General, with the approval of the Local Government Board. In order to render the crude death-rates strictly comparable they have been corrected or "standardised," the method adopted having been fully explained in the Registrar-General's Seventy-fourth Annual Report notices of which have already appeared in our columns.[1] To the practical sanitarian the last column of this table will be instructive. It gives a condensed record of the incidence of infant mortality in each of the four main divisions referred to. But inasmuch as each division contains administrative areas widely differing from one another as regards the social and sanitary circumstances of the inhabitants, which presumably determine the rate of infant mortality locally prevailing, we must wait for the detailed annual report for 1913, which will undoubtedly disclose much greater local differences in this respect than those mentioned in the table. In that report we may also expect to find particulars of the loss of life at the various stages of the first year after birth, as well as of the chief causes responsible for that loss in each of the 241 administrative districts of the country. On these several points information was given in the Registrar-General's seventy-fourth report already referred to.

THE CENTENARY OF CLAUDE BERNARD.

FRENCHMEN in all ages have been mindful of their great men's achievements, and memorials of one kind and another have been erected to those who by their work and their genius have helped the progress of human knowledge. Medical heroes have been duly honoured thus. It is always agreeable to stroll through the corridors of that heterogeneous mass of buildings which is the abode of the Medical Faculty in Paris. There are to be found the memorials to the investigators who have made the Faculty of Medicine of Paris one of the foremost in the world's history. Crossing the Boulevard St. Michel and passing along the Rue des Ecoles, immediately beyond the Sorbonne, we come to an institution of an entirely different kind. This is the famous Collège de France—with its 42 professorial chairs—an institution founded by François the First; over its main portal is its proud motto, "Omnia docet." In front on a sloping grassy enclosure stand two statues, one of Dante and the other of Claude Bernard. On Tuesday, Dec. 30th, 1913, a meeting was held to commemorate the centenary of the birth of Claude Bernard, though as a matter of fact Bernard was born in July. This ceremony, at once simple yet imposing, took place in Theatre

[1] THE LANCET, Nov. 22nd, 1913 (p. 1491), and 29th (p. 1566).

No. 6, in which Bernard experimented and where he expounded his famous discoveries. M. Poincaré, the President of the Republic, was present, and the seating accommodation was all occupied long before the appointed hour, at which the railed-off part of the floor space was filled by leading members of the medical and other professions. The chairman, M. Viviani, the Minister of Education and Fine Arts, delivered an eloquent tribute to the vast services rendered by Bernard to humanity. Bergson, professor of "philosophie moderne" in the Collège de France, read a short address, and Professor Gley spoke on some aspects of Bernard's work, as also did Professor Henneguy. Professor Dastre and Professor d'Arsonval—both former assistants of Bernard—gave their personal reminiscences, and eulogised not only his work but also the goodness of his nature, his great heart and noble soul. One interesting personality was not able by reason of infirmity to be present—viz., Professor L. Ranvier, one of Bernard's early assistants, for whom, largely through the influence of Bernard, the chair of comparative histology in the Collège de France was founded. A little volume on Bernard was written some years ago by Sir Michael Foster, although Foster never saw him; but the best account of Bernard's life work is that by Professor Paul Bert, "L'Œuvre de Claude Bernard." Bert unfortunately left physiology to take up a Government appointment in Tonquin, where he ended his days. Dastre succeeded him at the Sorbonne. Bernard himself was succeeded by Brown-Séquard at the Collège de France, and when the latter retired d'Arsonval was elected to the chair of medicine that had been occupied in succession by Magendie, Bernard, and Brown-Séquard.

THE AUSTRALIAN TRIBESMEN.

ON Tuesday evening, *Jan. 27th, Professor* Walter Baldwin Spencer, C.M.G., F.R.S., professor of biology in the University of Melbourne, delivered an address on the Life of the Australian Tribesmen before the Royal Anthropological Institute. Previous to his address, which was given in the theatre of the Civil Service Commission, Professor Baldwin Spencer was entertained by the Fellows of the institute at the Café Monico at a dinner, with Professor Arthur Keith, F.R.S., the president, in the chair. The address gave a most interesting outline of the life led by the primitive Australian savage. Professor Baldwin Spencer has intimate knowledge at first hand of the customs and characteristics of the natives of that continent, and his account of their life and surroundings was made more vivid by cinematograph and phonograph records taken by himself on the spot, as well as by lantern slides of the country and its primitive inhabitants. The large audience was first shown views of the plains of the southern part of the northern territory, and of the central ranges and the northern rivers to illustrate the environment of the Australian tribesmen. Then scenes of camp life and corroboree dances, and of the all-important ceremonies connected with totemic worship, were thrown upon the screen, accompanied by phonographic reproductions of the curious barbaric songs sung upon these occasions. By these means Professor Baldwin Spencer was able to bring his hearers into close touch with the domestic and ceremonial life of the indigenous peoples of Australia, whose habits and totemic ritual are of permanent interest to students of anthropology. It is evident that the scientific lecturer of to-day, if he cares to make use of them, has immense advantages over his predecessors.

AMERICAN MEDICAL MEN IN LITERATURE.

IT is both pleasant and profitable to recall the excursions and successes of members of our profession in fields outside of medicine. The ranks of the medical profession down the ages have afforded some notable examples of travellers and explorers, clerics and missionaries, military commanders, legislators and administrators, and in spheres more closely allied to medicine, scientists and litterateurs. "The recent death of Dr. Weir Mitchell suggests," writes a correspondent, "a few notes on some members of the American medical profession who have achieved local, and in some cases more extended, reputation in literature." He mentions merely those members of the medical profession in the western continent who have contributed to literature, including in the term only poetry, fiction and drama, history, biography, and the didactic and philosophic essay, and we take what follows from his communication. James Thacher (1754–1844), who entered the army as assistant surgeon the year before the declaration of independence, was a biographer and historian, and wrote also on demonology and superstitions and antiquarian subjects. Samuel Latham Mitchill (1764–1831), Professor of Chemistry at Columbia College, has a place in the late Clarence Stedman's "Poets of America." Lemuel Hopkins (1780–1801), an eminent consultant of Hartford, Connecticut, was a political satirist and a poet of some mark, his best known poems being "The Hypocrite's Hope," "The Cancer Quack," and "Ethan Allen." Usher Parsons (1788–1881) did some good work in genealogy and biography and history, and wrote on Indian names. He also published a novel, "The Avenger of Blood." Joseph Johnson (1776–1862) left besides essays a work of historical value in "Traditions and Reminiscences of the Revolution." James Gates Percival (1795–1856), Professor of Chemistry at the United States Military Academy, was a poet of mark, his best known works being "Prometheus," "Clio," and "Dreams of a Day." He also published two volumes of verse. Thomas Ward (1807–1873) composed many ballads and war lyrics, as well as comic operas, and certainly has a niche among American poets. Alfred Mercier (1816–1894) was of French descent, and was educated in France. He published in Paris in 1842 two poems, "La Rose de Smyrne" and "L'Ermite de Niagara," which received great praise. He has several novels to his credit, "Le Fou de Palerme," "La Fille du Prêtre," "L'Habitation de St. Ybars," and "Johnelle," the last named having been published in 1891. John Williamson Palmer (1825—1906) abandoned medicine altogether for literature in 1853, and travelled considerably in Europe and the East. He published a comedy, "The Queen's Heart," also "Folk Songs," and "The Poetry of Compliment and Courtship." He is one of the leading lyric poets of America. His poem, "Stonewall Jackson's Way," was written within sound of the battle of Sharpsburg. He anticipated Bret Harte as an interpreter of Californian life in such stories as "The Old Abode," "Mr. Karl Joseph Kraft of the Old Californians," and others.[1] The woman question evidently interested him, for he translated from the French Michelet's "La

Femme" and Legouve's "Histoire Morale des Femmes." His varied travels afforded material for "New and Old; or, California and India" (1859), and "Up and Down the Irrawaddi" (1860). Gustav Bruhl (1826–1903), a native of Prussia, settled in Cincinnati in 1848. Not only as a scientist and historian did he take rank; he was also a German-American poet of no mean order. His "Charlotte," "Die Heidin des Amazon," "Poesien des Urwalds," and "Abendglocken" call for mention. He was also an archæologist and anthropologist of note. Sir William Osler has made us familiar with Elisha Bartlett (1804–1855), whose essay on "The Philosophy of Medicine" is regarded by many as a classic in American medical literature, as is also his discourse on the "Times, Character, and Writings of Hippocrates." Orpheus Everts (1826–1903) was one of the early "problem novel" writers. His "Giles and Company" dealt with the problem of heredity, while "The Cliffords" was based on the relations of religion and science. He also published a volume of verse entitled "Facts and Fancies." Chandler Robbins Gilman (1802–1866) wrote "Life on the Lakes" and "Legends of a Log Cabin." We have not included Drummond, the poet of the Canadian habitant, for he was a Canadian, or Draper, the historian and philosopher, or Noah Webster, the lexicographer, historian, and essayist, or Oliver Wendell Holmes, who needs no introduction where the English language is read.

AN EPIDEMIC OF "SHIP FEVER."

THE old "ship fever," typhus, has of late years been little heard of, but if the former conditions of dirt and overcrowding arise again the disease will come back with them. All port medical officers must therefore have typhus fever in their minds, and will be obliged to Dr. Markl, health officer of the port of Trieste, for his account[1] of an epidemic which, arising in a crowded Turkish transport, came under his observation last summer. On [illegible] 14th the steamer *Vorwaerts* embarked at [illegible]na, in Albania, and at another port on the [illegible]atic, 2766 defeated Turkish troops, worn out [illegible] in misery. There were two doctors belonging to the ship and six Turkish doctors as well. 200 of the troops were sick, but their ailments were not exactly diagnosed, and though 27 died during the passage free pratique was at once granted the ship on her arrival at Constantinople on May 20th (sixth day). It was subsequently ascertained that while the soldiers were on board the crew had lived practically with them and all of them had become in consequence infested with lice. As soon as the troops were landed the ship returned to Trieste (May 25th, eleventh day), and there disembarked her trooping fittings and discharged half her crew before proceeding, on May 29th (fifteenth day), to Fiume, which she reached next day, when eight of the crew reported themselves sick and were diagnosed as suffering from malaria or three-day (pappataci) fever. On June 1st (eighteenth day) she was back again at Trieste with 14 sick on board, supposed by the visiting physician to be cases of some form of alimentary intoxication, and pratique was granted, when two of the sick landed and went to their homes. But when request was made for the admission of one of the crew to the city infectious hospital it was recalled that another of the men discharged from that ship on or about May 25th had been already taken ill with typhus fever, so the grant of free pratique was recalled and the ship isolated for the night in the roads. Next day (nineteenth day) she was again medically examined and 18 men on board were found to be sick, all, as it proved, with typhus fever. On later investigation it appeared that in each half of the crew, those discharged on May 25th and those still left on board, 20 cases developed, 40 in all, and that no case arose among those men who replaced the half first discharged—that is, the disease attacked those only who were on the ship with the Turkish troops, but did not spread from them to the men who came on board later. The symptoms were two or three days' feeling of illness, shivering, headache, and anorexia; one man had vomited; only four of the 18 were in bed, but all had more or less pyrexia and fast pulse, two had enlarged spleens, and four showed an exanthem (nineteenth day). On none were any lice found, the men having had time since May 20th to get rid of them. From not one single case, even from those nursed at their own homes, did infection spread—a strong corroboration, as Dr. Markl points out, to Nicolle's view that the infection of typhus fever is carried by lice, and that a patient may be harmless to his neighbours once he is freed from lice. It is noted how strikingly little subjective discomfort and feeling of illness there is at first, but the patients all complained of distressing sleeplessness and of bad dreams when they did doze. The exanthem is an inconspicuous roseola appearing on the fourth or fifth day, and first on the front of the chest and abdomen, becoming generalised later, and altering to petechiæ. Post mortem it is noticed at once that the blood is fluid, as is sometimes the case after death from suffocation; ecchymoses are seen on the surface of the liver and spleen, and the spleen is enlarged, weighing over ¾ lb. Death occurred in six of the cases described above (15 per cent.) from collapse, and in the majority of instances at the end of the second week. Injection of blood into guinea-pigs never set up the disease.

THE SIMPLES AND DRUGS OF INDIA.

FOR some 80 years—namely, from 1498 to 1580—the only European power holding any dominion in India was Portugal. Vasco da Gama anchored before Calicut in May, 1498; Francis of Almeida was the first Viceroy, from 1505 to 1509; while Goa was captured in 1510 by Alfonso de Albuquerque, the Portuguese domination being extended to various places on the Malabar and Malacca coasts. Goa became, as it still is, the capital of Portuguese India, and to Goa, in 1534, there came as physician to Martin Affonso de Sousa, afterwards (1542 to 1545) governor of the city, Garcia da Orta, author of a work written in dialogue form upon the Simples and Drugs of India.[1] The book was first printed at Goa by Johannes de Endem in 1563, being the third book ever printed in India. A Latin epitome made by Clusius (Charles de l'Escluze) was published by Plantin in 1567, which, says Sir Clements Markham, was very different from the original. The epitome was translated into Italian by Antonio Briganti (Venice, 1582) and into French by Antoine Colin (Lyons,

[1] Colloquies on the Simples and Drugs of India, by Garcia da Orta. New edition (Lisbon, 1895), edited and annotated by the Conde de Ficalho. Translated with an introduction and index by Sir Clements Markham, K.C.B., F.R.S. London: Henry Sotheran. 1913. Pp. 509. Price £2 2s. net.

1619), Orta's name being translated into Du Jardin. An inaccurate edition was published at Lisbon in 1872, and finally Count Ficalho published his standard edition in two volumes, 1891 to 1895, with valuable notes and comments, he himself being an accomplished botanist. The volume now before us is a translation of this edition. Garcia da Orta was born at Elvas about 1490, and from the evidence of the Colloquies is supposed to have studied medicine at the Universities of Salamanca and Alcala de Henares from 1515 to 1525. He then returned to Portugal and practised as a village doctor at Castello de Vide. In 1532 his patrons, the Sousa family, got him appointed lecturer in Lisbon University, a post which he held until 1534, when, as already mentioned, he accompanied Martin Affonso de Sousa to Goa. Here he practised as a physician until about 1570, when he died. The interlocutors of the Colloquies are Garcia da Orta and an imaginary person, by name Dr. Ruano, who is, says Count Ficalho, the personification of the literary and student side of Orta himself. Ruano is always referring to Pliny, Dioscorides, Serapion, Mesue, Avicenna, and other ancient authors, while Orta, though he occasionally mentions the ancients, says (p. 288), "I keep myself remote from these scholastic matters," and frequently when Ruano quotes the ancients in opposition to Orta the latter simply replies, "I [illegible]e seen it." The Colloquies are 59 in number, [illegible] deal mostly with vegetable drugs, though [illegible] animal drugs, such as ambergris, bezoar, and theriaca, are dealt with. There is also a Colloquy on precious stones and on pearls, which formed part of the *Electarium de gemmis* or Diamargariton of mediæval and later times. So Gilles de Corbeil in his directions for treating a rich patient says: "Contundat gemmas, molat aurum, misceat ambram." One Colloquy treats of cholera, another gives an account of a robbery committed by the aid of datura poisoning, and another of the Pao de Cobra, one of the many "Snake Roots," scientifically known as Pauwolfia Serpentina. Orta's style is occasionally somewhat confused. For instance, in talking of plants used for scent he says (p. 37): "Others are used for their scent, such as sandal wood, which is very commonly used to anoint the body, and the Linaloe, Amber, Almisque, and Algalia, much used because the price is not so high. This is because there are many cats in many parts of India." The argument appears a decided *non sequitur*—it may be one analogous to Darwin's well-known canon about cats and clover. The book on the whole is singularly interesting as giving a vivid picture of a physician's knowledge of Indian drugs in the sixteenth century. It is illustrated with pictures of various plants taken from the work of Cristoval Acosta, brother of the better known Josef Acosta, who wrote on Mexico. Cristoval published a work on the medicines of the East Indies at Burgos in 1578. The volume is beautifully printed, though we notice, surely, a misprint on p. 13, where the word "Greeks" in Ruano's first question should be "Turks." Again, on p. 28, in the Colloquy on *Amomum*—i.e., cardamum—Ruano quotes Mateolo Senense as saying that he "does not hold for certain that this drug enters into the *tiriaca* of Andronicus." In his index of persons Sir Clements Markham gives the name Andronicus (p. 28) and adds, "apparently a mistake for Marcus Aurelius." In our opinion there is no doubt that "Andronicus" is a mistake for "Andromachus." The Andromachi, father and son, were physicians to the Emperor Nero, and the father wrote a poem in Greek elegiacs, 'Αντίδοτος γαλήνη, which was quoted by Galen in the Liber de Theriaca ad Pisonem and was translated into Latin under the title De Theriaca. There were many Theriacæ in ancient medicine, but the most renowned were those of Andromachus and Damocrates.

"THE ISLE OF MAN."

Dr. Gustave Monod, M.R.C.S., M.R.C.P., the first Frenchman for 300 years to receive this combination of qualifications, has been studying post-graduate methods in England as a Government delegate, and on Jan. 22nd gave a demonstration in the Therapeutics Section of the Royal Society of Medicine of the "Peristaltic Movements of the Intestines of a Cat," thus showing his audience by the help of the cinema how vividly some physiological processes, not usually visible to the mind's eye, may be set before the student. Food passes from the stomach to the bowel of a cat more rapidly than through a dog or a human being, but when under the influence of senna, and in the conditions of a laboratory experiment, the feline gut performs with almost surprising *aplomb*. Thrown artistically upon a dark-blue screen the cat's intestines, in [illegible] tended or convulsed their convolutions. A futurist sculptor of the school of Mr. Epstein might have seen in the abbreviated drama of the descent of fæcal matter a subject quite as interesting as pregnancy or parturition, which the new art believes to be not unworthy of plastic representation. In the same drama an old Greek physician might have fancied that he beheld the writhings of the mystic serpent of healing. Indeed, one wonders whether the caduceus does not in some sort symbolise man's twining guts. Had it been possible, however, for old Phineas Fletcher to be present at the lecture he would have been more delighted than any of the audience. Fletcher is the poet of the Microcosm, and in "The Purple Island or the Isle of Man," published at Cambridge in 1633, he essays the bold task of describing man's inner economy, both anatomical and physiological. Following up a metaphor well known to Shakespeare and to the ancients, he portrays the body as a country with rivers, lakes, cities, and so forth, and a host of functionaries from the Steward Gustus down to the Porter. The stomach is the kitchen and the intestines are its drainage. His metaphor here is scarcely metaphorical enough. Some eight verses at the end of Canto II. describe the drainage system, over which Hepar, a great official, keeps spies:—

> These pipes are seven-fold longer than the Isle,
> Yet all are folded in a little pile,
> Whereof three noble are, and thinne; three thick, and vile.

The poem is not a success, for it fails to move us. Indeed, it is at best a "conceit" of a most ingenious kind. Poets are apt to be conventional in their thought, and they probably imagine that there is something shameful or terrifying in what happens inside us. Now, however, that there is a medical poet laureate someone may think of the possibilities of a poetry of medicine. Much verse has undoubtedly been written on specific diseases, such, for instance, as the famous "syphilis" epic. But the body in health has been left severely alone. Only one poem has come to our notice in recent years which in any way recalls "The Isle of Man." This is "The Unexplored Republic," which appeared in the *Speaker* shortly before the decease of that admirable literary weekly. The writer conceives of the brain as an unexplored country, governed in some mysterious way by a general consensus of individual cells. Pathos enters into such a theme when death is discussed and the decay of protoplasm considered.

Shall I then know when breeze and stream grow dumb,
And the bright frontier watchfires cease to shine,
And all my tiny citizens become
Doomed miners in a mine?

Shall I be given, or can they, dying, give
The sum of their small lives to be my spark,
So that my selfish spirit still shall live
When their small sprites grow dark?

How is Man's Immortality contrived?
How, if each live cell die, can I attain
Unto th' Immortal who am myriad-lived,
Of living cells a chain?

O darkling "Purple Island," still unknown!
O unexplored Republic, hard to span!
O complex Self unutterably alone,
O lone unfathomed Man!

FRACTURE DISLOCATION OF CERVICAL VERTEBRÆ WITHOUT INJURY OF THE CORD.

BEFORE the advent of skiagraphy little was known of fractures of the spine unaccompanied by lesions of the cord, for the reason that such could not be diagnosed. Now it is known that they frequently occur. Fracture dislocation of the cervical spine is usually accompanied by severe injury of the cord. In the *Australian Medical Journal* of Dec. 6th, 1913, Mr. Alan Newton has reported the following case exceptional to this rule. A man, aged 26 years, while cycling collided with a horse and cart. The horse's nose struck him on the back of the head, throwing him to the ground. He did not lose consciousness and at once regained his feet. He then felt severe pain in the upper part of the neck, most marked posteriorly and increased by even slight movement. On examination he was found to be muscular and well-nourished. The head was held immobile with the cervical spine in a position of slight extension. There was moderate tenderness over the spines of the second and third cervical vertebræ, but no deformity was noticed. Careful examination of the nervous system revealed nothing abnormal. A skiagram showed an injury much more considerable than was expected. There was fracture dislocation between the second and third cervical vertebræ. The pedicles of the second were fractured, and the body (in accordance with rule) projected forwards. However, the spinal canal was not encroached on, and to this fact the patient owed his life. The projecting body could be palpated through the pharyngeal wall. The treatment was immediate immobilisation of the neck by means of a plaster jacket extending from the vertex of the skull to the waist and rest in bed for two months. The jacket was then removed. Three months after the injury there was no pain or apparent limitation of the movements of the spine. A second case occurred in the practice of Mr. Fred Bird. A man, aged 25 years, while building a haystack, fell from the top to the ground, a distance of 12 feet. His brother ran to his assistance and found his head tilted forwards and to one side and held rigidly in that position. Thinking the patient was in danger of imminent death he seized his head and steadying it between his knees gave it a sudden twist. He heard a distinct click and at once the patient could move his head again. Some weeks later Mr. Bird saw him for neuralgic pains in the back of the neck and head in the course of the great occipital nerve. A skiagram showed a partial dislocation of the atlas on the axis and some crushing of the arch of the latter. After a year he had improved, but had not completely recovered. He occasionally suffered from pain and there was slight limitation of movement of the neck. The pain was no doubt due to pressure of callus upon the nerve.

PELLAGRA INVESTIGATION.

NOTWITHSTANDING the numerous researches which have been carried out in recent times concerning the etiology of pellagra, the real origin of that disease remains shrouded in mystery. We are not, however, without hope that before long some satisfactory solution of the problem may be forthcoming as our knowledge of the subject accumulates. Other diseases have seemed equally obscure, and for long years have puzzled investigators. Two instances which may be cited are beri-beri and endemic goitre, in both of which a satisfactory explanation of their causation has at last been found. There has been no lack of hypotheses advanced to explain the occurrence of pellagra in certain places, but so far none of those put forward have been supported by a sufficient weight of evidence to render them acceptable to scientific minds. Neither maize (spoilt or unspoilt), parasitic infection, nor a deficiency of some essential element in the dietary has yet been proved to be the true cause of pellagra, and until the causation of this mysterious malady is definitely known it is impossible to formulate the most appropriate measures for preventing it. For this reason any contribution to the general stock of knowledge respecting this disease must be heartily welcome at the present time. Among those who have taken a conspicuous part in this country in the investigation of pellagra Dr. L. W. Sambon comes in the first rank. It may be remembered that in 1912 he visited Italy and other parts of Southern Europe, on behalf of the British Pellagra Commission, to study the disease in some of its definitely recognised endemic areas, and to consider the conditions there in the light of his own hypothesis that pellagra was due to a parasitic infection transmitted to man through the agency of some insect, probably a species of simulium or sandfly. In continuation of these studies Dr. Sambon left England in August, 1913, on an expedition to the United States to inquire into the circumstances under which pellagra occurred in certain areas situated in the Southern States. By invitation he attended the American Pellagra Conference held in October at Columbia, South Carolina, taking part in the discussions and comparing notes with other experts. It appears that he found a number of American medical men disposed to believe in the parasitic theory of the origin of the disease, and able from their own experiences to find evidence which seemed to support it. He also examined the work that was being done by the Thompson-MacFadden Pellagra Commission in South Carolina and was much impressed with it. After leaving the United States he visited the Panama Canal Zone, *British Guiana*, and by request a number of ur West Indian Islands, in some of which he iscovered undoubted evidence of the presence f pellagra in localities where it had not een previously suspected to exist. Besides tudying that disease Dr. Sambon took the pportunity incidentally of gathering information oncerning some other tropical maladies, including lackwater fever, filariasis, elephantiasis, and eprosy. We now learn that he has recently returned o London, bringing with him a large amount of aluable material collected during his trip to the Vestern hemisphere. This information will, we nderstand, be embodied in a printed report which s expected to form an important contribution to the tiology and epidemiology of pellagra; its publication will be awaited with considerable interest by he medical profession of this country. It is right o mention here that it was due to the generosity nd public spirit of Mr. H. S. Wellcome that the xpedition of Dr. Sambon in 1913 to America became ossible from the financial point of view, and the ame remark applies equally to the expedition ndertaken by Dr. Sambon to Southern Europe in 912.

THE NATURAL PRESENCE OF BORIC ACID IN FOODS.

PURVEYORS of preserved provisions, or even of resh products which easily spoil, such as butter nd milk, make considerable use of various antiseptics. A certain number of these which have een found to be injurious to the public health re forbidden by the sanitary regulations of early all countries. When the toxicity is veak, but may yet appear cumulatively on daily se of the product, even though it be used in ninimum quantity, the percentage allowed is fixed y regulation. This is the case with sulphurous cid in wines, salicylic acid in beer and jams, and boric acid in provisions. When such a substance is examined by the police authorities in France and discloses a proportion of the antiseptic greater than the permitted strength a prosecution ensues, and in the case of an imported product its admission is refused. Two years ago the fruit crop was poor in France, and a large quantity of dried fruit and preserves was imported from Canada. Analysis showed a too great quantity of boric acid, and admission was refused by the Customs. The Canadian merchants protested that they had not added more boric acid than the regulations allowed, and an inquiry was held, the investigation being entrusted to Professor Gabriel Bertrand of the Institute Pasteur. Dr. Roux has recently reported the results of this investigation to the Académie de Médecine. It was shown that boron is found in all living cells. By means of a very precise quantitative analytical procedure, devised by M. Bertrand and M. Aiguilhon, it is possible in a few hours to determine the exact amount of boron contained in the natural product and to distinguish it from the boric acid artificially introduced. M. Bertrand thus found in each kilogramme of dried fruits 0·112 gramme of boric acid in the pulp of the apricot and in cherries, 0·028 gramme in the black grape, 0·0028 gramme in English pears. Nearly all vegetables—notably haricots, carrots, turnips, onions, gherkins—contain per kilogramme from 110 to 112 milligrammes. These findings will be most likely made the most of by food purveyors; but they will at least permit the establishment of a normal boric acid content, *beyond which the discovery of any* greater amount will justify a conclusion of adulteration. For boric acid to exercise adequate preservative properties it will have to be used in proportions greater than those shown by analysis to be present in the natural product. This case recalls the announcement made in our columns 11 years ago that salicylic acid would appear to be a normal constituent of most fruits, the quantity found, however, being very small and not exceeding one milligramme per kilogramme of fruit.

THE ACTION OF SODIUM BICARBONATE IN SHOCK.

IN the *American Journal of the Medical Sciences* Dr. M. G. Seelig, professor of surgery, St. Louis University, Mr. J. Tierney, and Mr. F. Rodenbaugh have published an important experimental study on the action of sodium bicarbonate in shock. In 1903 Howell found that sodium carbonate was an excellent cardiac stimulant in shock. In 1910 Henderson suggested, as a corollary to his theory that shock is due to loss of carbonic acid (acapnia), the prevention of such loss and its replacement by increasing the dead space of the respiratory tract. In the treatment of shock Howell obtained better results from sodium carbonate than from substances generally regarded as of value in this condition. Adrenalin, pituitrin, alcohol, and strychnine gave negative results, or at best temporary and unimportant rises of blood pressure. He thought that the pressor effect of sodium bicarbonate was due to its alkalinity. In order to check Henderson's theory of shock Professor Seelig and his collaborators introduced a solution of sodium bicarbonate into the blood, from which carbonic acid is set free by the action of three constituents—hæmoglobin, serum albumin, and acid sodium phosphate. Infusion of sodium bicarbonate caused a pronounced rise of blood pressure in dogs in a state of shock induced by manipulation and chilling of the abdominal viscera. A rise of 18 millimetres in the mercury manometer was the average, but a rise of 40 millimetres was not uncommon. Concomitantly with the rise of blood pressure there was an increase of the amplitude of the heart beats. This increase, as well as the rise in blood pressure, was well maintained for a fairly long period. On the other hand, the sodium bicarbonate appeared to have no effect on the rate of the heart beat. Another effect was an increase in the depth of the respiration. Evidently this was due to the action on the respiratory centre of the increased amount of carbonic acid in the blood, for an identical result was produced by injection of carbonic acid into the blood. But the rise of blood pressure was *not to be explained by* the same cause; in other words, by the acapnia theory of shock. For if this theory were correct the increased depth of respiration produced ought to have deepened the shock. The rise might be attributed to (1) the bulk of fluid injected; (2) hypertonicity of the injected fluid; (3) alkalinity of the injected fluid; and (4) influence of free carbon dioxide. The bulk of fluid would not explain the rise, because the amount used was small—in all cases under 26 c.c. and sometimes as low as 2 to 5 c.c. With regard to the second theory, it has been shown *that in shock plasma* escapes from the blood into the tissues and the specific gravity of the blood rises. It is possible that the introduction of a hypertonic solution into the blood might reverse the current and prevent the specific gravity of the blood from rising. That the rise of pressure was not due to this cause was shown by infusing dogs in a state of shock with hypertonic salt and basic sodium phosphate solutions. Practically no effect was produced on the low blood pressure. That alkalinity was not the cause of the rise was shown by infusing potassium hydrate and basic sodium phosphate solutions, which gave no rise. Finally, carbon dioxide gas was introduced into the femoral vein. It stimulated respiration most actively, but did not influence the amplitude of the pulse or the blood pressure. This seems to disprove Henderson's view that shock is due to acapnia. The direct vasomotor effect of sodium bicarbonate on the vessels was not tested, but Howell in working on sodium carbonate formed the impression that it acted solely as a cardiac stimulant. All other factors being excluded, it followed that sodium bicarbonate acted specifically on the heart muscle. This was corroborated by the fact that when both vagi were cut a rise of blood pressure followed its injection.

ST. GEORGE'S HOSPITAL.

WE have learned with regret that the Princess Christian has resigned the presidency of St. George's Hospital. A meeting of the house committee of the hospital took place on Wednesday last to consider Her Royal Highness's resignation, when the circumstances precedent, which are well known to all our readers from the full and frequent allusions in the press, came under discussion. The house committee passed a resolution universally regretting Princess Christian's decision, begging Her Royal Highness to reconsider it, and requesting that she would receive a deputation from them that their views might be laid before her. We understand that the existing house committee, any vacancies thereon being filled up, will remain in office until June; but a special court of governors will be held on Wednesday, Feb. 12th, when the proceedings will be open to the press.

Sir Richard Douglas Powell, Bart., M.D., will deliver two Emeritus Lectures on Fridays, Feb. 20th and 27th, at 3 P.M., in the large theatre in the Middlesex Hospital Medical School, "On the Therapeutic Use of Digitalis and Strychnia."

Sir StClair Thomson and Mr. Arthur Cheatle have been elected honorary members of the Società Italiana di Laringologia e Otologia, and Sir StClair Thomson has been elected an honorary member of the Berlin Laryngologische Gesellschaft.

WITH reference to the decision of the London County Council that it could not legally accept the ambulance service scheme prepared by the Metropolitan Asylums Board at the request of the Council, it was mentioned by the ambulance committee of the Board on Jan. 24th that when in 1903 the Board began the conveyance of non-infectious cases (mental, medical, and surgical) the service could have been easily extended to street accident cases. These, however, were purposely excluded because the County Council, in 1902, had undertaken an inquiry into the ambulance question. Eleven years had passed since then and it was to be regretted that London must now wait for a further indefinite period for a street accident service, which the Asylums Board was prepared to provide by midsummer, 1914. Although the County Council has now held two meetings since Christmas, there are no details of an ambulance scheme, promised to be reported immediately after the recess.

THE EXPERIENCES OF CAPTAIN SCOTT'S NORTHERN PARTY FROM A MEDICAL POINT OF VIEW.

THE large hall of the Royal Society of Medicine was completely filled on Monday afternoon, Jan. 26th, for an interesting lecture by Surgeon G. Murray Levick, R.N., Sir FRANCIS H. CHAMPNEYS, President of the Society, being in the chair.

Surgeon LEVICK said it had been suggested to him that as Captain Scott's northern party lived for some time under unusual conditions their experiences might interest the Fellows of the Society. There were six members of the party: Commander Campbell (in command), Surgeon Levick, Mr. Priestley, and three petty officers of the Royal Navy, who left New Zealand at the end of November. When they landed at Cape Adair they built their sectional hut. He did not believe there were stronger winds anywhere. A speed of 100 miles an hour was several times recorded before the wind-gauge was broken. The party had to crawl on all fours. The hut was anchored by wire hawsers to stakes in the ice, and a wind screen was erected sloping upwards to the roof of the hut. The rough seas threw up huge boulders, which subsequently froze together and formed large masses. In a couple of days the sea froze to a depth of 18 inches, sufficient for a sledging party to travel over. There were four months of darkness, during which they were unable to get away from the beach.

The clothing for the spring—which was the time of lowest temperature and strongest winds—consisted of thick woollen trousers and vest, a woollen jersey, and cotton windproof clothing; two or three pairs of socks, fur boots of reindeer hide, and a windproof helmet. A woollen nose-piece was also necessary. The weather was very treacherous. One might set out on a fine and promising day and in 20 minutes there would be a tremendous blizzard without warning, preventing one seeing a couple of yards in front. The party found some interesting fossil remains, one of which showed a tropical tree. When it became evident that the ship could not reach them they had only three weeks' full provisions left. The base at Cape Evans was 220 miles distant. They secured a number of old penguins, and though they were thin and had no blubber they formed an agreeable change from seal meat. Owing to the strong flavour of the seal blubber it was difficult to get used to, and the party had very little oil. At first they ate as much seal meat as possible, with resulting unpleasant symptoms. Until the end of July the party were on short rations and were perpetually hungry. They gradually introduced blubber 60 per cent. to 40 per cent. of meat Carbohydrates were missed very greatly. During seven months very little exercise was taken. Frostbites were always a result of going into the open.

When the supply of salt became nearly exhausted resort was had to salt-water ice. But this initiated a distressing epidemic of diarrhœa, and was discontinued for a week, and the remaining salt used, when the diarrhœa ceased, only to recur when the ice was resumed. In all respects except food, the party suffered all the conditions associated with the production of scurvy, but none had that disease. It seemed impossible to have scurvy while fresh meat was being eaten. While large quantities of seal meat were being taken, there was much uric acid in the urine, and the crystals made micturition distinctly painful. Several members suffered from enuresis in their sleeping bags, with serious results, the bags on awaking being found frozen hard. The desire to micturate became very acute and precipitate, quite out of proportion to the reason for it. These symptoms largely subsided on a low diet. Later every member suffered much from constipation, anal fissures, and hæmorrhages. A man would be absent for 40 minutes, and return in much pain, remaining in pain for hours. When they succeeded in securing more seals the resumption of hearty meals brought back the uric acid and other discomforts. They therefore boiled the meat for at least half an hour, and this caused a disappearance of the symptoms. If the meat was underdone or there were not facilities for cooking, the symptoms became once more evident.

The ventilation of the "igloo," or ice-cave, is an interesting question. To keep out the wind two doors, consisting of bags and boxes, practically shut out all air, and though six men slept in this confined space, 12′ × 5′ × 4′ 6″, no discomfort was felt, not even a headache. But a severe blizzard, combined with the glazing of the roof of the cave, due to the refreezing of the partially melted snow, prevented the permeation of oxygen through the drift snow into the igloo, and the lamp, the stove, and the match all refused to burn. This necessitated the making of a chimney through the drift snow. Surgeon Levick attributed the absence of asphyxial symptoms to the stimulant effect of the intense cold, but for which such foul air could never have been tolerated. Five months were passed in comparative health in these conditions, but as they felt they were going downhill the remaining two months, they decided to get away; and to fit themselves for the long sledge journey to the base they did Swedish exercises. By the time the journey was commenced they were fitter than they expected to be. He believed it was only the carnivorous diet which enabled them to pull through. After three days, during which they went very well, they began to weaken, but fortunately they found the depôt with many varieties of food left by Mr. Griffith Taylor's geological party. They all made an enormous meal, eating the frozen butter and lard like apples. Yet they woke up again in the middle of the night as hungry as ever, and partook of another heavy meal. A member of the party who had been ailing for weeks became quite well within 24 hours of his hearty meal, and finished up quite strong; the varied and plentiful diet had done more for him than all the remedies Surgeon Levick was able to administer. During several days they did 16 hours' marches each day, with only short intervals for food. The long journey home occupied five weeks.

The PRESIDENT conveyed to the lecturer, in the name of the audience, hearty thanks for his lecture.

MEDICINE AND THE LAW.

Dr. Arthur Drury v. Officers of the National Antivaccination League.

Dr. Arthur Drury, of Halifax, has recently agreed to the settlement of an action entered in the High Courts of Justice, King's Bench Division, against certain officers of the National Antivaccination League. The action is a sequel to a Government inquiry held by the Manx Legislative Council last year, at which Dr. Drury gave evidence in favour of vaccination. The *Vaccination Inquirer*, in July last, contained an article on Dr. Drury's evidence, which formed the subject of the action. In October the following article, headed "Dr. Drury and the *Vaccination Inquirer*," appeared in that paper:—

> Having regard to the freedom of the language frequently used by both pro- and anti-vaccinist controversialists, we are surprised to learn that Dr. Drury considers the remarks which we made in the July *Inquirer* on certain portions of his Manx evidence transgress the limits of "fair comment." We therefore wish to state that in using the words "dishonest" and "dishonourable," we had no desire or intention to make any personal imputations against Dr. Drury as a professional man. The context of those words clearly shows that they had reference only to the criticism of certain statements which Dr. Drury had made in regard to the *Vaccination Inquirer*, and that they were used in a controversial and not in a personal sense. As, however, Dr. Drury thinks that they are capable of an offensive interpretation, and that they reflect upon his character as a professional man, we readily insert this explanation, and express our regret if the use of these words has given Dr. Drury cause to complain.

This was regarded as wholly insufficient, and in December the defendants caused to be printed and published in the *Vaccination Inquirer* the following further apology:—

> We are sorry to learn that Dr. Drury is not satisfied with the explanation and expression of regret which we published in our issue of Oct. 1st, 1913, and we therefore desire to amplify our apology. We definitely and distinctly withdraw all the words in our article of July 1st which can be considered in any way to reflect on Dr. Drury either in his professional or personal capacity. We desire to express our regret that we allowed any words to be published which could cause Dr. Drury any pain or be considered in any way to reflect upon his integrity, and we make an unreserved and unconditional apology for having done this Owing to the correspondence that has taken place with Dr. Drury's solicitors, we were not able to insert the above apology in our November issue.

Later a settlement has been agreed upon on the following terms: 1. The payment to Dr. Drury of the sum of 100 guineas. 2. An undertaking that the publication shall not be republished. (The defendants state that the publication has already been withdrawn.) 3. The payment of costs in full. 4. The publication in the *Vaccination Inquirer* of the following:—

> Dr. Drury having taken exception to a certain article in the *Vaccination Inquirer*, an action was commenced in the High Court at his suit against the editor of the *Vaccination Inquirer* and certain officers of the National Antivaccination League. This action has now been settled by the apology and withdrawal which appeared in the *Vaccination Inquirer* of 1st December, 1913, defendants having paid to Dr. Drury 100 guineas as agreed damages and his costs of the action, and the issue containing the statements complained of has been withdrawn from publication.

5. An agreement that the terms of settlement may be published in the *Jennerian*, the *British Medical Journal*, and THE LANCET. Dr. Drury's case has been conducted by Messrs. Hempson, solicitors

(London), acting on behalf of the Medical Defence Union. We congratulate them on the result of their prompt and energetic action.

The Spreading of Scarlet Fever.

At the West London Police Court Mr. C. E. A. MacLeod was summoned for failing to notify a case of scarlet fever, and Mr. A. Samson, the employer of the patient, a domestic servant, for causing her to be placed in a public conveyance, a taxicab. After a son of Mr. Samson, who lives in Kensington, had suffered from scarlet fever and his room had been disinfected, a nurse in the defendant's service contracted the disease. Mr. MacLeod saw her and pronounced her to be suffering as stated, whereupon Mr. Samson sent her in a taxicab to her home at East Dulwich, to be there attended by her panel doctor. This gentleman ordered her removal to an isolation hospital and notified the case, but no notification was made by Mr. MacLeod. Mr. MacLeod, in giving evidence in his own defence, said that it never occurred to him to notify the case—the girl was not his patient; he was only asked to examine her, and he knew nothing about her being sent home in a taxicab. Mr. Fordham accepted this statement, but at the same time inflicted a fine of £1 with 23s. costs. The law allowed no alternative, but our readers will sympathise with Mr. MacLeod; he clearly did not see that the matter concerned him. Mr. Fordham commented severely upon the conduct of Mr. Samson towards both the public and the patient, fining him £5 with 3 guineas costs. It will be observed that there was no reason in this case why a medical practitioner upon the panel should not have attended the patient at her temporary address. But the spread of education has not yet made the public fear the spread of disease. In another recent case, also of scarlet fever, a young man was fined £1 for exposing himself when suffering from scarlet fever in a public-house at Hednesford, where he lived. This conviction was due to the public spirit and energy of the defendant's medical attendant, Dr. R. S. Harvey, who, not finding him at home in bed, followed him to the public-house, and upon his escaping thence pursued him on a bicycle till he finally caught him hiding behind a building.

Chilley v. *Bradford.*

An action was tried recently by Mr. Justice Darling and a special jury in which Mr. Victor Chilley sued Dr. A. Bradford as proprietor of a nursing home, in which the plaintiff had undergone an operation, for damages for the negligence of his servants. The plaintiff's case was to the effect that in order to have an operation performed upon his nose by Mr. C. A. B. Horsford he entered the defendant's nursing home about 2.30 P.M. and went to bed. A nurse named Stuart soon afterwards placed a hot water bottle in his bed and afterwards administered to him an injection of morphia. He went to the operating theatre about 5.30 feeling no pain in his legs or feet, returned to his bed, and went to sleep after the operation, which was successfully performed. When he woke up he found his legs and feet blistered from severe burns, apparently due to the hot-water bottle placed in the bed by the nurse. Evidence as to the duration of the heat in hot-water bottles placed in a bed was given with regard to this, and the fact that in the way indicated the plaintiff had been caused suffering was not seriously in dispute, the main question being the legal liability of the defendant for the negligence, if any, of a nurse in his employment in the circumstances in which the nurses of a nursing home are placed at the disposal of patients and of their own medical advisers. The defendant's case was that it was his duty not to nurse the plaintiff, but to provide competent nurses to do so under the direction of the plaintiff's medical adviser. In the end the following questions were left to the jury by Mr. Justice Darling: 1. Did Dr. Bradford undertake to nurse the plaintiff? 2. Was Nurse Stuart a qualified and competent nurse? 3. Was Nurse Stuart guilty of any negligence by which the plaintiff was hurt. 4. Was Dr. Bradford himself guilty of negligence and, if so, in what respect? 5. In ministering to the plaintiff was Nurse Stuart acting as the servant of Dr. Bradford? 6. What damages, if any, should the plaintiff receive? The jury answered questions 1, 2, 3, and 5 in the affirmative, 4 in the negative, and as to 6 awarded £100 damages to the plaintiff, for which judgment was entered. The above questions are quoted at length because it is from the points thus left to a jury that the nature of the liability and of the facts and conditions upon which a claim for damages must be based can best be gathered. Messrs. Le Brasseur and Oakley, instructed by the London and Counties Medical Protection Society, Limited, defended the action on behalf of Dr. Bradford.

Misconception of a Hospital's Functions.

At Stroud county court a dentist's assistant was sued for £17 by a medical man who had operated on the defendant's wife in the hospital. The defendant, who earned 2 guineas a week, said that he thought all attendance in hospitals maintained by voluntary subscriptions was free. His honour Judge Ellicott said that hospitals were maintained as charities to assist the extremely poor, and not for the benefit of those earning as much as £2 a week. He gave judgment for the plaintiff for the amount claimed. It cannot be pointed out too clearly that an understanding as to payment should be arrived at beforehand between medical man and patient in all cases where any misunderstanding as to liability is possible.

The Hopf Trial.

As already announced in THE LANCET of May 24th, 1913, p. 1495, a man in Frankfort had been arrested on suspicion of having killed his wife by inoculation with pathogenic bacteria and the internal administration of arsenic. During the investigation it appeared probable that he had on former occasions murdered other members of his family in the same way, and he had to appear recently before a criminal court in Frankfort charged with the murder of his father and his mother, two of his children and his first wife, and also with the attempted murder of his second wife and his third wife, the latter being now the only survivor of them all. His motive for doing so was that he wished to get the money for which the lives of his wives and children were insured and the inheritance of his parents. He had the body of one of his three wives cremated so that the cause of her death could not now be ascertained, but in the bodies of the children and of his first wife quantities of arsenic were found. The prisoner admitted that he had given arsenic to some of his family during their lifetime, not for criminal, but for therapeutic purposes, and also after death in order to prevent the body from decomposing. He denied having inoculated his wives with pathogenic bacteria, but stated that he had used such bacteria for experiments on dogs in connexion with his private studies, although he was neither a bacteriologist nor a medical man. The mental attitude of the man was extremely peculiar. He was absolutely calm and gave his answers without the least excitement. The bacterial cultures were purchased by him in Vienna because no German laboratory was willing to supply the cultures ordered by him under the name of an alleged scientific institution. After a trial lasting three days the jury found him guilty of the murder of his first wife, of the attempted murder of his second and third wives and of his two children, and not guilty of the murder of his parents. Medical experts declared that the man was not insane, but was in the full possession of his mental faculties. It is reported that the Austrian authorities will adopt legislative measures such as already exist in Germany to prevent pathogenic micro-organisms from being supplied to unauthorised persons.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR 1912-13.

I.

THIS report[1] forms a separate supplement to the forty-second annual report of the Local Government Board. Following the customary arrangement the volume begins with the report proper, in which the medical officer of the Board describes some of the outstanding features characterising the public health during the year, the principal matters which have been undertaken by the medical staff of the department, and the "auxiliary scientific investigations" which have been authorised under the annual Parliamentary grant. The report is followed by a large series of special returns, official circulars, &c., together with reports by members of the medical staff on such matters as the distribution of plague, cholera, and yellow fever, outbreaks of infectious diseases, offensive nuisances from trade processes, the work done by the branches for food inspection and vaccine lymph preparation, and the work of the pathological laboratory. Some of the reports on the auxiliary scientific investigations are also included and appear at the end of the volume.

The medical officer, Dr. A. Newsholme, devotes a large portion of his report to consideration of the local prevalence of tuberculosis and to the measures for its treatment and prevention which have followed the institution of "sanatorium benefit," while he also refers to some instructive results obtained by Dr. A Eastwood, Dr. A. S. Griffith, and Dr. F. Griffith in searching for evidence of tuberculosis in the bodies of children taken seriatim as they came for necropsy and irrespective of the causes of death. It will be convenient to review these sections of the report separately in the course of a subsequent article.

General Death-rate and Mortality according to Age.

After commenting on the reduction of death-rate from all causes and from infectious diseases which is apparent when the figures for 1912 are compared with the average experience of 1891–1900, Dr. Newsholme analyses the death-rate from all causes during the 11-year period 1901–1911 at the groups of ages 0–5, 5–10, 10–15, and 15–20. The result, as shown in a series of curves, is a steady improvement at each age, partly interrupted in 1911 in consequence of the exceptionally hot summer of that year. The fall in the mortality of infants under one year is particularly striking. Attention is drawn in this connexion to the special report issued last year on the incidence and causes of infant mortality in 241 urban areas in England and Wales,[2] and to the observations by Dr. T. H. C. Stevenson in the 1911 report of the Registrar-General for England on the statistics of infant mortality in the chief groups of occupations. Among the families of army officers in 1911 the infant mortality per 1000 births was only 44, of naval officers and solicitors 41, of medical practitioners 39. These figures must be compared with the average ratio of infant mortality among artisans of 113, among miners of 160, among unskilled labourers of 152, and among agricultural labourers of 97 per 1000 births. The rate for the middle classes generally was only 61 per cent. of the total mortality rate of the country among legitimate infants.

The report bears tribute to the value of the great alterations in the presentation of national statistics that have taken place in the office of the Registrar-General, and have borne fruit in the annual report of that officer for 1911. These reforms include the substitution of administrative for registration areas; the better allocation of deaths to the normal place of residence; the adoption of the international list of causes of death; the publication of a number of rates annually and a standardised death-rate for each area of sanitary administration; the comparison of mortality from numerous diseases and from all causes in large geographical divisions; and the attempt to analyse the relative frequency of complications and sequelæ in acute infectious diseases.

Pathological Means for Diagnosing Disease.

The Departmental Committee on Tuberculosis in their final report stated their opinion that, in addition to the research work they proposed out of the funds provided under the National Insurance Act, there should be a general extension throughout the United Kingdom of clinical laboratories for the better diagnosis and treatment of disease. Dr. Newsholme gives in an appendix to his report the replies to a general circular sent to county and county borough councils inquiring the extent to which laboratory aids to diagnosis have been supplied by them. These aids were found to be limited in the main to enteric fever, diphtheria, and tuberculosis, examination for other infectious disease being rarely undertaken. The work, as a whole, was carried on in much larger amount in the boroughs than in the counties, and in each group great variations were met with in the extent to which bacteriological work was undertaken and utilised. Dr. Newsholme contrasts these municipal and county undertakings with the much wider field which is covered in the laboratories of most voluntary hospitals, from some of which special returns were obtained, and states his view that in order that a satisfactory medical service may be secured throughout the country facilities for work similar to that being done in hospitals will need to be offered to medical practitioners generally.

Acute Infectious Diseases.

The behaviour of certain of the acute infectious diseases since 1901 is considered seriatim, mainly by comparison of the mortality rates for England and Wales. The decline in the mortality rates of scarlet fever, diphtheria, and enteric fever has in each instance been conspicuous. Under diphtheria reference is made to an example of continued presence of diphtheria bacilli of proved virulence in the throat of a patient eight months after attack, and to the occurrence in the rural district of Saffron Walden of 15 cases of the disease traceable to a patient discharged from hospital who proved to have a suppurating sore on the scalp which contained virulent diphtheria bacilli. In regard to enteric fever, the mortality of which in 1912 was only one-fifth of what it was in 1881–90, the volume contains some very instructive reports from the medical inspectors of the department, which in most cases were separately published last year and then received notice in THE LANCET. These include an investigation by Dr. S. W. Wheaton of an outbreak in Strood (borough of Rochester) due to the pollution of a public water-supply from a well sunk into the chalk close to a number of soakaway cesspools and drains to which cesspools were connected; an extensive outbreak of enteric fever in the small Hampshire town of Ringwood, traced by Dr. H. A. Macewen to drinking water derived from a small stream which passes through the village; an epidemic in Colne in Lancashire, investigated by Dr. J. R. Hutchinson and referred to milk from a farm at which an unsuspected case of enteric fever was present; another in Harwich and its neighbourhood, in which Dr. S. M. Copeman ascertained that the outbreak had its origin in the supply of milk derived from a farm on which there was some reason to suspect that a temporary milker was a carrier case and had caused the infection; and finally a very instructive case of carrier infection by means of milk occurring in the West Riding of Yorkshire and investigated by Dr. Copeman in conjunction with Dr. Sutherland, the assistant medical officer of health of the county. The condition of the carrier in this case presumably dated back to an attack of enteric fever in 1906, since when she appears to have been responsible for five separate appearances of enteric fever involving from first to last about 60 cases in different sanitary districts. On two of these occasions her employment at dairy farms had given opportunities for infection to be conveyed by means of milk to a considerable number of persons outside the household in which she was living.

Duration of the Enteric Fever "Carrier Condition."

A supplement to the report, by Dr. J. C. G. Ledingham, gives the result of the bacteriological examination of fæces and urine from patients who had been discharged from the Metropolitan Asylums Board's hospitals convalescent from enteric fever. These patients were followed up in their homes by several of the metropolitan medical officers of health, and the examinations were facilitated by the fact that for two years, from February, 1909, to February, 1911, Dr. G. E. Cartwright Wood had systematically examined specimens from all enteric fever patients on their discharge from the Asylums Board hospitals. Thus in the collection of material from cases which had resumed their ordinary vocations, it was possible to obtain a series divided into two groups: the larger, in which the hospital results on discharge were negative, and the smaller, in which they were positive. Rejecting for comparative purposes all cases in which less than three examinations, at intervals of a month or longer after discharge, were made, Dr. Ledingham obtained 148 cases, of which 99 fell in the first group and 49 in the second. The first group was found to contain no carriers, while in the second eight cases were found, in three of which the carrier condition was probably only temporary, and in five more permanent. In one case the carrier condition remained after a period of over three years. The conclusion may be drawn that if, on sufficient and competent examination of the excreta of enteric fever cases at the time of convalescence, the result is negative, the subsequent development of the carrier state is improbable; if, on the other hand, it is positive, the possibility of the carrier condition remaining requires to be taken into serious account. Dr. Newsholme points out that Dr. Ledingham's observations tend to simplify the work of the medical officer of health who desires to follow up convalescent enteric fever cases in order to take precautions against carriers. He also insists on the importance of action to prevent the carrier case from being employed in the preparation of food, and commends the action recently taken in Manchester to make small weekly payments to a carrier known to have caused enteric fever, on condition that the woman in question stopped keeping lodgers, a business on which she was formerly dependent.

Measles.

A curve of measles mortality in England and Wales from 1881 onwards is given, which shows that since 1896, while the usual biennial augmentations of this disease have occurred, the greater and more formidable epidemics characteristic of some earlier periods have not reappeared, and as a whole the range of the measles death-rate has been at a lower level. London suffered severely from measles in 1911, but the death-rate in that year, 0·57 per 1000, was greatly exceeded in 1898 and in some previous years. Dr. Newsholme observes that it cannot at present be affirmed that the reduced death-rate from measles will persist, but it appears likely that the general improvement in hygiene and in the care of the sick has had a material influence in reducing the death-rate from this disease. Notwithstanding this reduction, measles is still sufficiently formidable, and caused 12,696 deaths in England and Wales, including 1790 in London, during 1912. Compulsory notification of all recognised cases of measles under the Infectious Disease (Notification) Act has not in the past had any marked success, and a number of local authorities who had added measles to the list of notifiable diseases have since obtained the sanction of the Local Government Board to revoke the order requiring this notification. Dr. Newsholme remarks, however, that probably the notification of the first cases in a family by the medical attendant or by the parent would be helpful, and notes that the city of Manchester has recently obtained powers making it obligatory on the parents of all children suffering from measles or whooping-cough to notify the cases.

The volume contains the report of an inquiry under the Board's scientific grant which was undertaken by Dr. H. Thursfield regarding the bacterial causes of death in measles. The disease is fatal principally through broncho-pneumonia and other complications, and it is possible that it is the secondary infections associated with these complications more than the measles organism itself which are mainly responsible for the fatal result. Dr. Thursfield, who adopts this hypothesis, studied a series of measles cases fatal from broncho-pneumonia, and his results indicate that the death is most frequently associated with septicæmia set up by streptococcus pyogenes (18 out of 31 cases), and less often with pneumococcus infection. The latter appeared principally in the cases which died comparatively early, at the end of the first or beginning of the second week. The bacillus influenzæ also was found to play a part in the production of broncho-pneumonia. The suggestion is made that measles cases in which streptococci are found in the fauces should be strictly isolated from other measles patients, and that in measles generally more attention should be paid to cleansing the fauces and mouth than is now usually the case.

Cerebro-spinal Fever and Poliomyelitis.

Under this heading the report contains instructive diagrams of notified cases of these diseases week by week during 1912, distinguishing those in urban and in rural districts. In 1910 and 1911, when epidemic poliomyelitis was ascertained to be present in considerable amount in England and Wales, the cases were observed chiefly in country districts and in small towns. In 1912, on the contrary, 135 cases were notified in London, 586 in provincial urban districts, and 118 in rural districts; in terms of population approximately twice as many cases were observed in urban as in rural districts. From a separate statement supplied by Dr. R. J. Reece it appears that, judging from the notifications, the fatality of poliomyelitis was 13 per cent. and that from cerebro-spinal fever 70 per cent. About three-fourths of the poliomyelitis cases were children under 5, and in at least half of the total cases of this disease permanent paralysis of one or more groups of muscles occurred. Dr. Newsholme advises that medical officers of health should exercise some measure of supervision over children who have in recent months suffered from this disease, in order to advise parents to secure the best treatment available.

Small-pox; Vaccination Returns; Vaccine Lymph.

Only 121 cases of small-pox were notified in England and Wales in 1912; single cases or small groups of cases occurred in London in two metropolitan boroughs, in 32 sanitary districts in the provinces, and in six port sanitary districts. A somewhat greater prevalence occurred in Bristol. All but six of the total cases were isolated in hospitals, and an appendix to the report analyses the condition of these cases in respect of their vaccination. Another appendix gives a digest of the local vaccination officers' returns with regard to children whose births were registered in 1911. For England and Wales the percentage of "acceptance" of vaccination was 52·3 in that year, continuing the fall which has set in since 1905, when the corresponding figure was 75·8. The official returns relate only to children whose births are registered within a given 12 months, and take no cognisance of later vaccinations under the influence of local apprehension of small-pox, but they show undoubtedly that "the proportion of the population which is not protected against small-pox by vaccination is slowly increasing." During the 12 months ended March 31st, 1913, 615 public vaccinators received special awards under Section 5 of the Vaccination Act, 1867. Dr. F. R. Blaxall reports on the work of the Government Lymph Establishment; over 384,000 tubes were sent out during the year, and used principally for primary vaccinations, which gave a case success of 99·4 per cent., and an insertion success of 93·1 per cent.

Epidemiology of Plague, Cholera, and Yellow Fever.

After referring to the work of the International Health

Office, to which the Local Government Board furnishes the British representative, the report epitomises the study of the prevalence of plague, cholera, and yellow fever throughout the world in 1911 and 1912, which has been made by Dr. R. Bruce Low, and occupies a large section of the volume. This collection of information as to the prevalence, rise, and fall of these diseases in different countries must have entailed a great amount of labour and constitutes a very valuable record. In regard to plague, it is interesting to note that in India, where the deaths numbered over 800,000 in 1911, the disease now seems to be somewhat rapidly subsiding.[1] Fortunately, the terrible experiences of Manchuria in 1910-11, when over 50,000 persons died from pneumonic plague, were not repeated, and beyond some scattered cases nothing was heard of plague in this northern province of China up to the end of 1912. The account of cholera includes a description of the methods adopted at New York in 1911 to detect carrier cases among emigrants from the Mediterranean ports by means of rectal swabs. The director of the State laboratories boarded the vessel with a supply of tubes of culture media and sterile swabs, and the passengers were brought to him one by one with loosened clothing. As they successively bent over a chair the director inserted his swabs with a single movement and with such dexterity that, it is said, 265 specimens could thus be obtained in an hour. Altogether about 27,000 persons were examined, of whom 26 were said to have proved infected by cholera. An account of the world prevalence of yellow fever is for the first time added to this series.

RESCUE APPARATUS FOR USE IN POISONOUS ATMOSPHERES.

A RECENT law has placed upon owners and managers of coal-mines the onus of providing portable apparatus to enable rescue work to be conducted in mines where the atmosphere at the moment may be irrespirable. But no steps have been taken to ensure that the apparatus provided shall conform to any definite standard of efficiency, or that the men who may be called upon to use it shall be properly trained beforehand in its technique. As a matter of fact, several valuable lives have been lost in late years through misplaced confidence in rescue apparatus of various kinds; more, probably, than have been saved by the same means. In these circumstances the Doncaster Coal Owners' Committee commissioned Dr. J. S. Haldane to investigate the various types of such rescue apparatus which are on the market, to report on their relative merits, and to point out such defects as he might discover in them. By the courtesy of the committee a copy of Dr. Haldane's report has been submitted to us; and we learn also that in three months' time he will repeat his tests to ascertain whether effective improvements have been introduced by the manufacturers. Meanwhile, Dr. Haldane is carrying out researches upon the smoke helmet and reviving apparatus.

The report now before us begins by recapitulating in simple form the admitted facts of physiology as they concern the respiratory interchange of gases in various states of rest and exercise. From this are deduced the minimum requirements of oxygen supply to, and carbon dioxide absorption from, a man who may have to do hard physical work in an irrespirable atmosphere for as long as two hours at a stretch. Then some five forms of patent apparatus are subjected to practical tests with a view to discovering how they comply with those requirements, and how they compare respectively for portability, reliability, safety, convenience, durability, and similar important factors. The results are of great theoretical interest and of even greater practical importance. All the five forms of apparatus possess such grave faults that none of them earns Dr. Haldane's approbation. Each has its own definite merits in various respects, but in certain particulars not one of them is satisfactory, so that a mere combination of the best points of each would not alone provide the perfect instrument. Stress is also laid upon the necessity for complete familiarity with his apparatus on the part of any man who risks his life underground by wearing one in a poisonous atmosphere; in other words, of the all-importance of preliminary training. Dr. Haldane well points out that vision and hearing must be left as free as possible. When penetrating along mine roads wrecked by an explosion or damaged by fire, steam, and so on, it is essential to avoid loose timber or stone projecting from the roof. Any man of over average height who has been down a coal mine will remember, doubtless, that only about 5½ feet separate the floor and the roof. Not only may a man who cannot see clearly when wearing a rescue apparatus bring down upon himself an avalanche of rock or timber, but he is also even more likely to injure himself or his apparatus by collisions with the walls or roofs of the gallery he is working in. Hence, Dr. Haldane disqualifies the smoke-helmet type of apparatus, preferring the mouthpiece pattern. A half mask is more comfortable than the latter, but less efficient in his judgment. It is also undesirable that the apparatus should project from the head or shoulders of the wearer; some of those which Dr. Haldane tested were greatly superior in this requirement to others. The oxygen cylinder type is better than that in which liquid air is employed in that it can be quickly put into use or out of use, whereas liquid air takes time to get going and cannot be prevented from wasting when its use is temporarily suspended. Another important quality of the ideal apparatus is that it should be capable of being easily, quickly, and certainly tested when required in an emergency: there are some intricate details connected with this point attention to which is vital. Again, the apparatus should be invulnerable to moderate trauma, since knocks and jolts are inevitable in the nature of things when it is in use. It should be undisturbed by high temperatures, and as incapable as may be of leakage. Finally, it must fulfil the physiological requirements already mentioned.

"It is quite evident," says Dr. Haldane, "from the results of our experiments that a number of serious and more or less dangerous defects exist in rescue apparatus at present in use in this country and in the manner of using them. The sooner these defects are recognised, the sooner will they be remedied, or adequate means be taken to guard against harm resulting from them." With this opinion, after reading Dr. Haldane's account of his experiments, it is impossible to disagree. Medical men, who are best qualified to comprehend his account of the physiological requirements and his criticism of the ways in which they are at present violated in rescue apparatus, might well turn their inventive powers to the problems thus presented, for not only is there the surety of fame for the successful inventor, but of material prosperity as well.

WEST AFRICAN MEDICAL STAFF DINNER.—The winter dinner of the West African Medical Staff, which took place on Jan. 21st at the Grand Hotel, London, W.C., was a pleasant and sociable function, distinguished by a degree of camaraderie resembling that to be found in a well-conducted regimental mess, rather than the stereotyped formality that so often characterises the ordinary banquet. Dr. W. T. Prout, C.M.G., medical adviser to the Colonial Office, presided, the vice-chair being occupied by Mr. J. P. Fagan, late deputy P.M.O. for Northern Nigeria. The unusual and highly commendable feature of the West African dinners is the fact that speechmaking is curtailed to the minimum After the Royal toast the President briefly proposed the toast of "The West African Medical Staff." Notwithstanding the existence of certain grievances, he said, the service was a very good one—a sentiment which received the cordial support of those present. Mr. G. Fitzjames Darker proposed the health of "The Guests" in a cordial and kindly manner, which was responded to by Mr. Kenneth Millican and by Mr. Pontifex, the latter of whom, in detailing the services rendered by medical science, unintentionally occasioned great merriment by citing as an instance the fact that sanitation had materially decreased the "birth" rate. The company then retired to the ante-room, where the rest of the evening was spent in clublike intercourse. Before the meeting broke up Mr. H. A. Foy proposed the health of Mr. Fagan, to whose unremitting zeal and energy the success of this dinner, as of many preceding ones, was due, and Mr. Fagan replied in a very humorous speech. The attendance was fair, though not so large as it ought to have been, considering the number of officers from the coast home on leave.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8490 births and 6098 deaths were registered during the week ended Saturday, Jan. 24th. The annual rate of mortality in the 96 or 97 towns, which had been 18·6, 19·3, and 17·0 per 1000 in the three preceding weeks, rose to 17·5 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these towns averaged 17·9, against 18·6 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 7·8 in Leyton, 8·6 in Ilford, 8·8 in Edmonton, 9·0 in Cambridge, and 9·3 in Walthamstow, to 24·3 in Plymouth, 24·5 in Bath, 24·7 in Rotherham, 26·1 in Barnsley, and 26·7 in Wolverhampton.

The 6098 deaths from all causes were 181 in excess of the number in the previous week, and included 343 which were referred to the principal epidemic diseases, against 355 and 329 in the two preceding weeks. Of these 343 deaths, 79 resulted from whooping-cough, 70 from measles, 68 from diphtheria, 68 from infantile diarrhœal diseases, 41 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual deatn-rate from these diseases last week was equal to 1·0, against 1·0 and 0·9 per 1000 in the two preceding weeks. The deaths attributed to whooping-cough, which had been 76, 64, and 66 in the three preceding weeks, further rose to 79 last week; of this number 15 were recorded in London, 7 in Birmingham, 6 in Manchester, 6 in Sheffield, 4 in West Ham, 4 in Liverpool, and 3 each in Leicester, Leeds, and Swansea. The deaths referred to measles, which had decreased from 80 to 55 in the four preceding weeks, rose to 70 last week, and caused the highest annual death-rates of 1·4 in South Shields, 1·6 in Rhondda, 1·8 in Great Yarmouth, 2·0 in Dudley, 2·8 in Burnley, and 6·8 in Barnsley. The fatal cases of diphtheria, which had risen from 60 to 70 in the four preceding weeks, were 68 last week, and included 13 in London, 7 in Manchester, 5 in Leeds, and 3 each in Tottenham, West Ham, Portsmouth, and Nottingham. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 80, 89, and 80 in the three preceding weeks, further declined to 68 last week, of which 14 were recorded in London, 7 in Birmingham, 7 in Manchester, 3 in Liverpool, 3 in Salford, and 3 in Rhondda. The deaths referred to scarlet fever, which had been 34, 43, and 37 in the three preceding weeks, rose to 41 last week, and included 6 in London, 6 in Birmingham, 4 in Salford, and 3 in Merthyr Tydfil. The fatal cases of enteric fever, which had been 16, 28, and 21 in the three preceding weeks, further fell to 17 last week, of which 3 occurred in London, 3 in Sheffield, and 2 in Salford.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily decreased from 4143 to 3676 in the seven preceding weeks, had further declined to 3567 on Saturday last; 375 new cases were admitted during the week, against 425, 416, and 388 in the three preceding weeks. These hospitals also contained on Saturday last 1077 cases of diphtheria, 239 of whooping-cough, 64 of enteric fever, 55 of measles, and 1 of small-pox. The 1577 deaths from all causes in London were 108 in excess of the number in the previous week, and corresponded to an annual death-rate of 18·2 per 1000. The deaths referred to diseases of the respiratory system, which had been 423, 511, and 400 in the three preceding weeks, rose to 421 last week, and were 68 above the number recorded in the corresponding week of last year.

Of the 6098 deaths from all causes in the 97 towns, 207 were attributed to various forms of violence, and 493 were the subject of coroners' inquests. The causes of 47, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, and in 59 other smaller towns. Of the 47 uncertified causes of death, 16 were recorded in Birmingham, 13 in Liverpool, 2 in Dudley, 2 in Burnley, and 2 in South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1167 births and 919 deaths were registered during the week ended Saturday, Jan. 24th. The annual rate of mortality in these towns, which had been 20·3, 20·2, and 20·4 per 1000 in the three preceding weeks, further rose to 20·9 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these towns averaged 20·5, against a corresponding rate of 17·9 per 1000 in the 97 large English towns. Among the several Scotch towns the death-rate last week ranged from 12·6 in Motherwell, 13·8 in Perth, and 14·0 in Kirkcaldy, to 26·8 in Greenock, 27·1 in Hamilton, and 32·3 in Kilmarnock.

The 919 deaths from all causes were 23 in excess of the number in the previous week, and included 100 which were referred to the principal epidemic diseases, against 79 and 67 in the two preceding weeks. Of these 100 deaths, 51 resulted from measles, 19 from diphtheria, 15 from scarlet fever, 9 from infantile diarrhœal diseases, 5 from whooping-cough, and 1 from enteric fever, but not one from small-pox. These 100 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·3, against 1·0 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 50, 36, and 29 in the three preceding weeks, rose to 51 last week, of which 25 occurred in Glasgow, 5 in Edinburgh, 5 in Greenock, 4 in Leith, and 3 in Ayr. The deaths referred to diphtheria, which had been 12, 14, and 13 in the three preceding weeks, rose to 19 last week, and included 5 in Glasgow, 5 in Edinburgh, 5 in Aberdeen, and 2 in Dundee. The fatal cases of scarlet fever, which had been 7, 9, and 8 in the three preceding weeks, rose to 15 last week; 5 deaths were registered in Glasgow and 4 in Aberdeen. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 11, 12, and 8 in the three preceding weeks, were 9 last week, of which 4 were recorded in Glasgow, 2 in Paisley, and 2 in Greenock. The deaths referred to whooping-cough, which had been 5, 5, and 9 in the three preceding weeks, declined to 5 last week, and included 2 in Glasgow. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had steadily increased from 139 to 230 in the five preceding weeks, were again 230 in the week under notice; 26 deaths were attributed to different forms of violence, against 33 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 618 births and 550 deaths were registered during the week ended Saturday, Jan. 24th. The annual rate of mortality in these towns, which had been 25·7, 25·4, and 21·6 per 1000 in the three preceding weeks, increased to 23·8 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these Irish towns averaged 23·6 per 1000; in the 97 large English towns the corresponding rate did not exceed 17·9, while in the 16 Scotch towns it was equal to 20·5 per 1000. The annual death-rate last week was equal to 28·4 in Dublin (against 18·2 in London and 20·6 in Glasgow), 23·8 in Belfast, 24·5 in Cork, 16·5 in Londonderry, 14·9 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 18·8 per 1000.

The 550 deaths from all causes were 50 in excess of the number in the previous week, and included 39 which were referred to the principal epidemic diseases, against 44 and 38 in the two preceding weeks. Of these 39 deaths, 10 resulted from whooping-cough, 9 from infantile diarrhœal diseases, 8 from measles, 7 from diphtheria, 3 from enteric fever, and 2 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·7 per 1000; in the 97 large English towns the corresponding rate did not exceed 1·0, while in the 16 Scotch towns it reached 2·3 per 1000. The deaths attributed to whooping-cough, which had declined from 10 to 4 in the four preceding weeks, rose to 10 last week, and comprised 5 in Belfast, 2 in Dublin, 2 in Tralee, and 1 in Lisburn. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 6, 7, and 11 in the three preceding weeks, fell to 9 last week, of which 5 were recorded in Dublin. The fatal cases of measles, which had been 7, 8, and 6 in the three preceding weeks, rose to 8 last week, and included 4 in Dublin. The deaths attributed to diphtheria, which had been 7, 6, and 2 in the three preceding weeks, rose to 7 last week, of which 6 occurred in Dublin and 1 in Lisburn. The deaths referred to scarlet fever, which had been 3, 13, and 12 in the three preceding weeks, declined to 2 last week, both of which were registered in Belfast. Of the 3 fatal cases of enteric fever 2 were recorded in Dublin and 1 in Belfast.

The deaths referred to diseases of the respiratory system, which had been 162, 154, and 130 in the three preceding weeks, rose to 153 in the week under notice. Of the 550 deaths from all causes, 167, or 30 per cent., occurred in public institutions, and 14 resulted from various forms of violence. The causes of 20, or 3·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1913.

(*Specially compiled for* THE LANCET.)

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1913.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the metropolitan boroughs and in the City of London. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 9·0 per 1000 of the population, estimated at 4,518,191 persons in the middle of last year; in the three preceding months the rates were 7·7, 10·4, and 11·0 per 1000 respectively. The lowest rates last month were recorded in the City of Westminster, St. Marylebone, Holborn, the City of London, Stepney, and Greenwich; and the highest rates in Fulham, Southwark, Bermondsey, Lambeth, Battersea, Camberwell, and Woolwich. The prevalence of scarlet fever showed a considerable decline from that recorded in either of the two preceding months; this disease was proportionally most prevalent last month in Hammersmith, Fulham, Southwark, Bermondsey, Battersea, and Camberwell. The Metropolitan Asylums Hospitals contained 3810 scarlet fever patients at the end of last month, against 2552, 3517, and 4006 at the end of the three preceding months; the weekly admissions averaged 445, against 402, 512, and 581 in the three preceding months. Diphtheria was rather less prevalent than it had been in either of the two preceding months; the greatest proportional prevalence was recorded in Paddington, Lambeth, Camberwell, Deptford, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 909, 1190, and 1188 at the end of the three preceding months, had declined to 1099 at the end of last month; the weekly admissions averaged 146, against 147, 184, and 158 in the three preceding months. Enteric fever also showed a diminished prevalence as compared with the two preceding months; this disease was proportionally most prevalent last month in Islington, Finsbury, Bermondsey, Wandsworth, and Lewisham. There were 51 enteric fever patients in the Metropolitan Asylums Hopitals at the end of last month, against 56, 77, and 72 at the end of the three preceding months; the weekly admissions averaged 9, against 11, 12, and 11 in the three preceding months. Erysipelas was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Camberwell, and Deptford. The 39 cases of puerperal fever notified during the month included 4 in Fulham, 4 in Stepney, and 3 each in Kensington, St. Pancras, Shoreditch, Wandsworth, and Lewisham. Of the 5 cases of cerebro-spinal meningitis, 2 belonged to Southwark, and 1 each to Islington, Finsbury, and Bethnal Green; and of the 13 cases of poliomyelitis 3 belonged to Lambeth and 2 to St. Pancras.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the population of the several boroughs. During the five weeks ending Jan. 3rd the deaths of 6437 London residents were registered, equal to an annual rate of 14·9 per 1000; in the three preceding months the rates had been 13·3, 13·7, and 13·5 per 1000 respectively. The death-rates last month ranged from 11·0 in Lewisham, 11·5 in Wandsworth, 11·8 in Hampstead, 12·6 in Chelsea, and 13·1 in Lambeth, to 17·1 in Poplar, 17·2 in Holborn, 17·4 in Bermondsey, 17·6 in Southwark, 19·4 in the City of London, and 19·7 in Shoreditch. The 6437 deaths from all causes included 300 which were referred to the principal infectious diseases; of these, 20 resulted from measles, 23 from scarlet fever, 50 from diphtheria, 50 from whooping-cough, 14 from enteric fever, and 143 from diarrhœa and enteritis among children under two years of age. The lowest death-rates from these diseases last month were recorded in Kensington, Hammersmith, the City of Westminster, Greenwich, and Woolwich; and the highest rates in Paddington, Fulham, Stoke Newington, Shoreditch, Bethnal Green, and Bermondsey. Only 20 fatal cases of measles were registered last month, against a corrected average of 221 in the corresponding period of the five preceding years; of these 20 cases 6 belonged to Camberwell, 4 to Southwark, 3 to Deptford, and 2 to Battersea. The deaths from scarlet fever numbered 23, the corrected average being 24; 3 cases belonged to Southwark, and 2 each to Paddington, St. Marylebone, Islington, Hackney, Poplar, Lambeth, and Camberwell. The 50 fatal cases of diphtheria were 11 below the corrected average number, the greatest proportional mortality from this disease being recorded in Paddington, Fulham, Stoke Newington, and Shoreditch. The 50 deaths from whooping-cough showed a decline of 20 from the corrected average number, and caused the highest death-rates in Fulham, St. Pancras, Finsbury, Shoreditch, Bethnal Green, and Poplar. The 14 fatal cases of enteric fever were 3 below the corrected average number, and included 3 in Battersea, 2 in Wandsworth, and 2 in Lewisham. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Fulham, Stoke Newington, Finsbury, Shoreditch, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was more than 60 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: G. Gibson to the *Indomitable* and F. J. Burns to the *Orion*, both on recommissioning. Staff-Surgeons: S. H. Vickery to the *Orion*, on recommissioning; and R. S. Osborne to the *Victory*, additional, for the *Birmingham*. Surgeons: A. R. Price to the *Indomitable*, on recommissioning; and C. V. Griffiths to the *Pembroke*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain William J. S. Harvey to be Major (dated Jan. 14th, 1914). Supernumerary Lieutenant Percival D. Warburton is restored to the establishment (dated Jan. 24th, 1914).

Supernumerary Lieutenant George E. Dyas is restored to the establishment (dated Jan. 24th, 1914).

Lieutenant Sumner H. Smith is confirmed in his rank.

Colonel F. H. Treherne, honorary surgeon to the Viceroy and Governor-General of the East Indies, has taken up duty at Meerut Cantonment as Assistant Director of Medical Services, vice Colonel E. Butt. Colonel C. Birt has relinquished the appointment of expert in tropical diseases to the Army Medical Advisory Board.

Lieutenant-Colonel D. Shanahan, on return home for duty from the Ninth (Secunderabad) Division of the Southern Army in India, has been appointed to the Eastern Command. Lieutenant-Colonel G. A. T. Bray has been selected for appointment as Deputy Surgeon to the Royal Hospital at Chelsea, vice Lieutenant-Colonel H. E. Winter. Lieutenant-Colonel J. M. F. Shine has been appointed to hold charge of the Military Hospital at Nowshera Cantonment. Lieutenant-Colonel H. I. Pocock has joined at Murree. Lieutenant-Colonel R. J. Copeland has taken up duty on the Headquarters Staff at York as Medical Inspector of Recruits to the Northern Command. Lieutenant-Colonel E. Eckersley has been placed under orders for transfer from the Seventh (Meerut) Division to the Fourth (Quetta) Division of the Southern Army in India. Lieutenant-Colonel H. M. Adamson has been selected for appointment to hold charge of the Military Hospital at Belgaum Cantonment. Lieutenant-Colonel G. F. H. Marks has joined at Dalhousie. Lieutenant-Colonel T. Du B. Whaite has been placed under orders to embark for a tour of service in the Third (Lahore) Division of the Northern Army in India.

Major M. Babington has been selected for appointment as Clinical Pathologist to the Queen Alexandra Military Hospital. Major M. J. Cromie has been placed under orders to embark for a tour of duty in the West Indies. Major J. A. Turnbull has been appointed to Kamptee Cantonment. Major J. V. Forrest has taken up duty in the London District. Major E. McDonnell has been transferred from Lydd to the Military Hospital at Shorncliffe. Major D. Harvey has been selected for appointment as Clinical Pathologist to the Royal Army Medical College at Millbank, vice Major J. C. Kennedy, who has embarked for a tour of service in India. Major W. C. Croly has taken up duty at Mount Abu. Major W. P. Gwynn has been appointed to the Dublin District. Major N. H. Ross has embarked for a tour of duty in India. Major H. G. F. Stallard has been transferred from Peshawar Cantonment to the Military Hospital at Mhow Cantonment. Major P. S. O'Reilly has taken up duty at Gravesend. Major E. E. Parkes has been ordered to embark for India. Major F. Harvey has embarked for a tour of service in India. Major E. P. Connolly has been transferred from the Military Hospital at Murree to Rawal Pindi Cantonment. Major A. H. Safford has taken up duty at Lucknow Cantonment. Major J. S. Bostock has been appointed to the Aldershot District. Major A. W. A. Irwin has been transferred from the Military Hospital at Clonmel to Limerick. Major G. A. Moore has been selected for appointment as Specialist in Otology to the Cambridge Military Hospital at Aldershot. An exchange has been approved on the roster for service abroad between Major L. Humphry and Major A. W. Hooper, D.S.O.. Major W. S. Harrison has been placed under orders to embark for a tour of service at Jamaica. Major W. R. Blackwell has been appointed Senior Medical Officer on board the transport s.s. *Rohilla* which left Karachi for Southampton on Jan. 16th with tour-expired troops.

Captain M. J. Lochrin has arrived home for duty from India. Captain T. H. Scott has been appointed to the Northern Command. Captain E. D. Caddell has been transferred to the Home Establishment. Captain H. Gall has

joined at Sialkot. Captain D M. Middleton has arrived home for duty from India. [illegible] T. [illegible]
been appointed to the Eastern [illegible]

2nd Welsh Field Ambulance, Royal Army Medical Corps: Arthur Frederick Bernard Shaw to be Lieutenant (dated Dec 8th, 1913)

Welsh Clearing Hospital, Royal Army Medical Corps. Captain Ashley Bird, from the List of Officers attached to Units other than Medical Units, to be Captain (dated Dec. 20th, 1913)

ROENTGEN SOCIETY —The next meeting of this society will be held on Tuesday, Feb. 3rd, at 8 15 P M., at the London Hospital, Whitechapel, when Dr Gilbert Scott will conduct visitors over the X Ray and Electro Therapeutic Departments of the hospital, give a demonstration of the Wilson Portable Coil Apparatus, and show a number of plates The honorary treasurer of the society, Mr C. E S Phillips, Castle House, Shooter's Hill, Kent, reminds members that their annual subscriptions are now due.

THE SIXTH INTERNATIONAL CONGRESS OF SOCIAL WORK AND SERVICE —Under the patronage of the King and Queen, and the presidency of Prince Arthur of Connaught, an International Congress dealing with State, municipal, and voluntary social work will be held at the London University, South Kensington, W., in the week ending June 5th, 1915 An executive committee, with Sir William J. Collins as chairman, has been formed, and among the members of the committee is Sir Shirley F Murphy. The subjects at present selected for discussion are: (1) Thrift in its Relation to Relief; (2) International Provisions for the Assistance of Deserted Children, (3) The Assistance of Families of Prisoners and Extradited Persons; (4) The Care and Control of the Mentally Defective (general reporter Sir H. Bryan Donkin); (5) *State Insurance* and Hospitals; (6) The Relation of the Municipality to Public and Private Assistance; (7) The Housing of the Working Classes; and (8) The Work of School Care Committees The membership subscription is 20*s*. All communications with reference to the congress should be addressed to the secretary or the treasurer at Denison House, Vauxhall Bridge road, London, S W.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 205.)

XXXV.—LONDON: EVIDENCE IN FAVOUR OF THE ACT.

LONDON is so huge that a feeling of bewilderment naturally assails the bold individual who would attempt to describe what is happening in that vast metropolis even though called upon to deal with but one subject. But it must be remembered that, when that subject is the health and the maintenance of health of all employed persons under the income-tax limit, we are dealing with a matter whose bearings and ramifications are boundlessly extensive.

Again, it is particularly hard in London to draw general conclusions on anything; much of one's experience must be secured from isolated and individual circumstances. There is no place in the world where it is easier to hide than London, as every criminal knows. Neighbours do not fraternise with each other and there is little local life developed by local spirit. Nowhere do people live such isolated lives; and therefore investigations are specially difficult for want of connecting links which enable the investigator, when once started, to go from one to the other end of a chain till he has covered the ground mapped out. Still, it is easy to see in regard to our present subject, the working of the Insurance Act, that the dividing lines are very sharply defined in London. The partisans of the Act and the opponents of the Act do not merge. On the contrary, they are drawn up in battle array against each other. There is in London no mere reluctance to work the Act, but associations are specially organised in opposition of the Act. By such bodies the panel doctors are still denounced as traitors to the flag, and this is no mere outburst of fervid oratory, but is expressive of deep conviction. As a result of such denunciations, or rather it may be fairer to say of the spirit which has led to their utterance, the London panels are understaffed. Then while doctors have been refusing to serve, insured persons have, on their side, refused to avail themselves of the services of the panel doctors. As a consequence, a huge unallotted fund has accumulated, and the law does not say with sufficient distinctness how this money is to be utilised. Nevertheless, and though there are so many insured persons who keep away from the panel doctors, some of these practitioners have a far greater number of insured persons on their list than should be allowed.

Unequal Distribution of Doctors and Patients.

At the end of December, 1913, there were 1370 doctors on the London panel which corresponds with the London County Council area. Of these, 92 were medical officers of hospitals, asylums, and various institutions. For the ordinary panel practice there were 1278 medical men available and there are a little more than 1,500,000 insured persons. If evenly divided each insurance doctor should have 1161 persons on his list and an income of a little over £400 a year. But the insured persons are not evenly divided, and a quarter of a million, or a sixth of the total, have not selected any panel doctor whatsoever. That would mean an average of but 1000 per panel doctor, or £350 a year. Such averages, however, are utterly misleading when it comes to actual practice, for in London there are many panel doctors who have not 500 insured persons on their list, while others have several thousands. In one case the tremendous figure of 6000 is said to have been reached. The argument has been presented that many insured persons do not trouble to select a panel doctor before they are ill. In support of this contention it is stated that 75 per cent. of the insured who had inscribed their names on a doctor's list sought his advice during the course of the year. But if this was the reason why so many insured persons have as yet no doctor, it would be the same in all parts of London. The contrary is the case. It is in the better class residential suburbs, and especially in the West-end, where practitioners are much more numerous than elsewhere, that a very large amount of insured persons, and far more than a sixth of the total insured inhabitants of those quarters, have not thought fit to select a panel doctor. It is in districts where the Act is not popular that so many of the insured will not avail themselves fully of its benefits. Political antipathy, or perhaps a question of social prestige, and not freedom from illness accounts for the fact that a quarter of a million Londoners have not yet selected their panel doctor.

As an unfortunate contrast to this state of things it is just where there are the fewest doctors that the insured persons have displayed the most readiness to inscribe their names. Indeed, one of the great difficulties is the uneven distribution of medical practitioners over London, and one of the good effects of the Insurance Act is that it will tend towards at least a partial remedy of this defect. I have been told that in Shoreditch there is only one medical practitioner for every 5000 of the population. On the other hand, in Kensington there is one doctor for every 500 inhabitants.

The National Insurance Practitioners' Association.

When the British Medical Association was organising resistance against the measure in its earlier stages there was in London a conviction that a large body of practitioners were anxious to take service under the improved Government terms. It was very evident that in the industrial areas the income and the sense of security of the working man's doctor would be greatly improved. Any amount of bills were never paid; the medical practitioner lost his drugs and got nothing for his time or trouble. If the thought that very probably the patient would not pay his bill could be removed the doctor would not hesitate to attend. Secure in the possession of a sufficient, even if still a modest, income, the poor man's doctor should certainly be better able to put his heart into the work, and vast multitudes throughout the East and industrial districts of London get better medical attendance than they had ever enjoyed before. With the prospect of such solace where it is most needed, the demurring of practitioners more favourably situated in respect of *clientèle*, but who feared to lose fees from a proportion of their patients now coming under the operation of the Act, might well be ignored, said those who were reconciled to the extension of contract practice by the promises of reform which it offered. A movement was started to protect those practitioners who were anxious to go on the panel.

The National Insurance Practitioners' Association came into being early in December, 1912. A month, however, had barely elapsed when the British Medical Association itself withdrew from its attitude of uncompromising opposition and allowed its members to go on the panel. Thus the newly formed National Insurance Practitioners' Association lost its principal *raison d'être* before it had time to come completely into being. It determined to cease active propaganda, but to maintain a watching brief. New members who offered to join were not encouraged, I am told, and after the month of May last were positively refused. There was, indeed, not much active work to do. In London, as in Edinburgh, a very large number of practitioners refused to join the panel, but in the greater part of the country the resistance melted away. The association was to have helped the victims of adherence to the principles of the Act, but there seemed very few victims. At first some doctors were boycotted because they had enrolled themselves for panel service, but it is impossible to say that much overt hostility of this sort went on. Consequently the new association devoted its energies to improving the conditions of panel practice. They were thus mainly instrumental in doing away with the huge book in which detailed entries had to be made, and substituting for it the much simpler record card system. In December, 1913, after having lived for just one year, the National Insurance Practitioners' Association decided that it had fulfilled its mission and that its continued existence was no longer needed. The society dissolved, its members being advised to join the British Medical Association and the Local Panel Committees. It is to these committees that the practitioners who are working the Act in London seem principally willing to entrust their future prospects. The British Medical Association, although it has in part absorbed the National Insurance Practitioners' Association, is accused of being under the guidance of members of the profession not personally involved in the working of the Act, so that it cannot properly understand the position of a great majority of practitioners who hold modest positions and do the hard and least agreeable work. The British Medical Association, I have been told more than once by those who are strongly in favour of the Act, has closed its eyes to the alleged fact that at least 10,000 medical practitioners in the kingdom were not only willing to go on the panel, but so realised the great advantages held out to them that nothing could possibly keep them away from accepting service under the Insurance Act.

Improvement of Poor Practices.

The practitioners in the industrial districts are so much better off now that they can afford to refuse badly paid work. Where a practitioner was ready and willing to accept midwifery cases paid at from 10*s.* to 15*s.*, he is to-day asking for a guinea or 30*s.* This would have caused ill-feeling, were it not that the poor can see two sides to the matter. Formerly a poor family would pay the medical attendant very inadequately, 10*s.* to 15*s.* out of their meagre wages. To-day the maternity benefit supplies enough money to pay the doctor adequately. Formerly the fee would cost the family perhaps more than a week's wages. If the poor used to pay less they had to save to pay, and had not the right to expect such good attendance as that to which they are now entitled, nor was there a great force of public opinion behind them to raise a storm if they were not properly treated.

The quality of service given in return for the better and safer pay has been questioned, but I have come across, or been told of, little unedifying behaviour on the part of panel practitioners. But whether it be in regard to midwifery cases or other cases, I was very positively assured that no practitioner who does his work well need fear coming up before the Medical Service Subcommittee to answer a charge of neglect. The laymen who participated in such inquiries were keener than the medical men themselves in detecting flaws in the evidence. I was very emphatically assured that the laymen on the London Insurance Committee showed the greatest consideration for the medical profession. There were no complaints that the medical men's point of view had not been properly considered. Even in the rather difficult question of prescribing no trouble has arisen. The drug bill for London may exceed the eighteenpence per insured person, but it is still hoped to save threepence out of the floating sixpence, and these threepences come up in London to a total of close upon £19,000 to be added to the income of the panel doctors.

Under these greatly improved financial conditions it is maintained that the poor and industrial districts of London have now a fairly well paid medical service. What is in colloquial parlance termed "a rotter" cannot be regenerated by an Act of Parliament. Granted that there are black sheep among the medical profession—and of course there are, but the proportion is most creditably small—the modern doctor, the newly qualified practitioner, who enters upon his career need no longer degenerate as he used to do through service in an East-end dispensary. The sixpenny doctor is dying out because he can now afford to refuse patients who want to pay less than 1s. As the pay improves so will the attendance improve. Thus the claim that the health of the people is better cared for gains fresh force in these facts.

Such is the story from one point of view. In my next article I propose to give an outline sketch of the motives and methods of those who have resisted the Act in London.

(To be continued.)

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Moritz Katzenstein, *privat-docent* of Surgery, and Dr. Max Zondek, a well-known surgeon, whose specialties are kidney and bone operations, and Dr. Oskar Wagener, *privat-docent* of Otology, who has been temporarily lecturing in the Greifswald University, have been granted the title of Professor. Dr. Arthur Pappenheim, whose researches on the pathology of the blood in the "second" medical clinic of the Charité have received a good deal of attention, has been recognised as *privat-docent* of Medicine.—*Breslau:* Dr. Gustav Drehmann, a well-known orthopædic surgeon, and Dr. Hans Aron, formerly professor of physiology in the Manila University, also Dr. Karl Hueter, prosector of the Municipal Hospital, Altona, have been granted the title of Professor.—*Konigsberg:* Dr. Walter Carl has been recognised as *privat-docent* of Surgery.—*Leipsic:* Dr. Georg Herzog has been recognised as *privat-docent* of Pathological Anatomy and General Pathology.—*Pavia:* Dr. Giuseppe Mariani has been recognised as *privat-docent* of Dermatology and Syphiligraphy.—*Prague (German University):* Dr. W. Rubeska, *privat-docent* of Midwifery and Gynæcology, has been granted the title of Professor.—*Rome:* Dr. Paola Alessandrini has been recognised as *privat-docent* of Neurology.—*Salamanca:* Dr. Santamaria has been appointed to the chair of Clinical Medicine.—*Shanghai:* Dr. H. Dold, *privat-docent* of Hygiene and Bacteriology in the University of Strasburg, has been offered the chair of Hygiene.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LEEDS.

Adoption of the Notification of Births Act, 1907.

THE city council, acting as the local authority for the city of Leeds, have adopted the Notification of Births Act, 1907, and by order of the Local Government Board this came into force in the city on Jan. 1st. A circular has been issued from the Town Clerk's office and sent to all medical men within the borough, setting out the provisions of the Act and the duties falling to be carried out by medical men in connexion with its adoption in Leeds. A covering letter from the medical officer of health has accompanied each circular asking for the coöperation of the profession in the working of the Act. Dr. J. Spottiswoode Cameron especially asks that medical men will indicate those cases in which a visit from one of the women inspectors would be of benefit. Of these women inspectors, who have done much good work in Leeds, there are at present six. These have under them four probationers, and it is the intention of the authorities to increase the number both of the trained inspectors and of those who are learning the work. The adoption of the Act in Leeds will, it is hoped, be attended with a lessening of the death-rate of infants, and may lead to an improved physique, especially among the lower classes.

The Leeds Public Dispensary.

The annual report of this institution shows a continuance of the useful work of the charity. In addition to a large out-patient department a very important part of the work consists in the attendance on necessitous patients in their own homes. Last year the number of visits made was 6760. Certain changes in the staff which have recently taken place should be mentioned. Mr. Michael A. Teale, who was appointed ophthalmic and aural surgeon some ten years ago, has resigned his position. It is Mr. Teale's intention to give up the practice of his profession and devote himself to art. Those who have been associated with Mr. Teale in his work and have known its excellence cannot but view his decision with regret, though they know that it is based on a long-cherished desire, and though they may see for him a successful career in his new work. With Mr. Teale's retirement Leeds finds itself without a member of the Teale family in active practice. This has not been the case for 116 years, for about the year 1797 Mr. Teale's great-grandfather began practice in the town. I have just been informed by Mr. T. Pridgin Teale that some of the patients seen by his grandfather had been attended to by his son during the earlier years of his work. Mr. Pridgin Teale is happily still with us, and though for a good many years he has been living in retirement from his profession he continues to take a keen interest in medical matters, and especially in those dealing with medical education. The vacancy created by Mr. Teale's resignation has been filled by the election of Dr. Harry Lee, and Mr. Teale was elected a member of the honorary consulting staff. As honorary physician Dr. J. le Fleming C. Burrow has been appointed to fill the position vacated by the resignation of Dr. G. W. Watson. Mr. A. Richardson takes the place of Mr. G. L Wells, whose death we have had recently to lament.[1] Dr. J. Godwin Greenfield has been appointed pathologist.

Jan. 27th.

MANCHESTER.

School Children and Cinematograph Shows.

THE Lancashire elementary education subcommittee has conducted an inquiry as to the effect of cinematograph shows on children attending the elementary schools of their area. Practically all the head teachers in the districts in which such shows exist agree that the shows are physically detrimental to the scholars in consequence of late hours, loss of sleep, and bad atmosphere. The subcommittee's finding is:—

> While conceivably cinematograph shows might be of some little use if arranged specially for educational purposes, it is doubtful whether, even then, the gain would outweigh other disadvantages. Under present conditions in the county there is no doubt that they serve no real educational good purpose.

In 28 districts there were 86 shows. The headmasters report that the majority of the children who attend these shows belong to the poorest families, and that over 50 per cent. regularly visit them. A number go three times a week and some every evening to the various houses. As to the effects on the children, the report says:—

> The pictures shown have lowered the moral sense; scholars think less of cruelty, lying, deception, and even theft; the children are less thrifty, they value money lightly, and derive a thirst for pleasure and amusement; some children actually steal to find money for admission.

In the opinion of the medical staff definite fatigue is caused by attendance at the shows, and the children who attend them are usually pale and tired. More especially in the smaller districts, where the picture houses are adapted buildings, there are overcrowding and bad ventilation, causing fatigue and favouring the spread of infectious diseases. It is proposed to send a copy of the report to the clerks of the county justices with a request that the latter will bring it forward when the time arrives for granting licences.

Notification of Births Act in Salford.

The Salford town council has decided to adopt the Notification of Births Act, and when the Local Government Board has announced its consent the Act will be put into operation. This Act was passed in 1907. Salford, however, had a method of its own for the notification of birth. When the Act is in force notification will be compulsory.

Measles to be no longer Notifiable in Oldham.

The Oldham health committee has decided to withdraw measles from the list of notifiable diseases.

Manchester Hospitals and the Need of Radium.

It has been suggested that a joint effort should be made in Manchester by the hospital boards to obtain a supply of radium for the treatment of malignant disease. It would appear that there are only two hospitals in Manchester in which hitherto any use has been made of radium—the Christie Cancer Hospital and the Skin Diseases Hospital By a combination of the friends of the hospitals it is suggested that a sum of £4000 should be raised by subscription in order to obtain at least two separate quantities of 100 milligrammes each. Should the money be subscribed and the radium obtained, it is further suggested that a small joint committee should have control of its use, so that precedence shall be given to the most needy cases and to those in which there would be the greatest likelihood of good results. The question of raising a public fund to secure a supply of radium for the treatment of malignant and cancerous diseases in Manchester is under consideration by the board of the Royal Infirmary, which institution in 1912 had between 400 and 500 in-patients under surgical treatment for cancer, besides out-patient cancer cases and those undergoing X ray treatment, which rose in number from 32 in 1909 to 107 in 1912.

Jan. 27th.

BRISTOL.

Research in Bristol.

THE Colston Research Fund Committee, administering money handed to it by the University Colston Society of Bristol, has reported on another year's work. The report bears witness to the activity and catholicity of the spirit of investigation in Bristol. Among the researches that have been supported there are several of medical interest. The department of physiology is responsible for inquiries into the nature of surgical shock, the principles of rectal alimentation, industrial fatigue, and the auriculo-ventricular connexions of the human heart. This latter investigation derives its significance from the fact that it was Professor A. F. Stanley Kent, who now describes connecting tracts between auricle and ventricle other than the auriculo-ventricular bundle, who was responsible for the original discovery of that bundle. The establishment of these facts must lead to important modifications in modern cardiac pathology. Professor F. H. Edgeworth's work on the cranial muscles and their nerve-supply is also alluded to; and work is being carried on in the pathology department in regard to dental bacteriology. A typhoid carrier has apparently been cured, after many efforts, by the use of a specially prepared autogenous bacterial emulsion. Other subjects which bear indirectly on medicine are the effects of small electric currents at low voltage on micro-organisms, the work of M. Nierenstein in regard to the manufacture of cheese and the chemistry of the commercial tannins, and the principles of soap manufacture. It is clear that there is a group of practical investigators at work in Bristol, and that they have good premises to work in will be granted by anyone who inspects them. An important addition to the resources for medical research is the new pathological department of the General Hospital, while the chief handicap to original work in the field of medicine lies in the strong opposition, which is still maintained by a few influential people, to experiments on animals. Happily there are signs of a more enlightened attitude, and with this obstacle removed much should be achieved. Recently Professor F. Gowland Hopkins, representing the National Insurance Research Committee, visited the Bristol laboratories and made many useful suggestions as to the possibilities of organised and assisted research.

Somerset County Tuberculosis Sanatorium.

At the last meeting of the Somerset county council the Insurance Act Tuberculosis Subcommittee presented its report recommending the adoption of a site near Wells. An amendment asking for expert opinion on this site (which is alleged to be too low, too near the Sedgemoor marshes, and difficult as to drainage and water-supply) was defeated by 41 votes to 10, the majority evidently feeling that sufficiently expert opinion had already been expressed in favour of the site.

Bristol Insurance Committee.

Among the many data disclosed by the chairman of this committee in his recent references to the past year's work it is interesting to note that less than 12 per cent. of the deposit contributors, who number about 2500, had applied for sickness benefit. He also stated that there were 916 notifications of tuberculosis during the year, 376 of them among insured persons and 540 among the uninsured.

Lord Mayor of Bristol's Hospital Sunday Fund.

The collections for this fund were taken on Sunday last and the Lord Mayor has issued his appeal for help, which describes the work done by the four chief institutions (the General Hospital, the Royal Infirmary, the Children's Hospital, and the Eye Hospital), and states that they need an increase of £9000 in their annual income. As usual, the number of patients who attended during 1912 is used as a basis for this appeal. Last year the introduction of the National Insurance Act did not affect the collections as was feared; and this year's appeal points out that the Act has in no way lessened the need for special treatment such as the institutions alone can give.

Bristol Dispensary.

The work of this institution was sensibly diminished during 1913 as a result of the introduction of National Insurance. It is clear, however, from the remarks made by Mr. Fenwick Richards, the chairman, at the annual meeting, that not everyone has yet assimilated the idea that persons insured against sickness under the Act are provided for in respect of ordinary illness and therefore not in need of institutional medical care except under special circumstances. He asked subscribers to find out whether those who applied to them for dispensary notes were really in need of them, and a little care at this stage of the application would save the dispensary, as well as the applicant, a good deal of trouble.

Bristol Eye Hospital.

At the annual meeting of this institution the report which was read showed an increase in the amount of work done. There were 522 in-patients and 8559 out-patients; this included 140 operations for cataract and 3400 refraction cases. The total ordinary income was £2276 and the expenditure £2727; this sum shows, as the Lord Mayor remarked, that the hospital is economically managed, and he appealed for an increase in the list of annual subscribers.

Bristol Eye Dispensary.

The chief features of the annual report are that the number of new cases was 2946, a slight decrease as compared with 1912, owing partly to the Insurance Act and partly to an arrangement with the education authorities whereby refractions in school children are done elsewhere; the election of Mr. H. G. Doggett to the presidency in the room of Mr. P. J. Wasley, resigning after 20 years' service; and a favourable balance of £9 on the year's work.

Jan. 27th.

IRELAND.

The Certification Question.

THE outstanding question arising from the National Insurance Act and concerning the medical profession in Ireland for many months back has been that of payment for certificates given under the Act. It was hoped last August, when Mr. Lloyd George promised to find a sum of money sufficient to meet the demands of the profession, that a speedy settlement would be arranged. I understand that for some months past important negotiations have been proceeding between the Insurance Commissioners and the medical profession, and that, on the whole, the progress of the discussion was encouraging to the profession. It was confidently hoped that a scheme satisfactory to all parties would be settled. Having heard the opinions of the medical profession, I understand that the Commissioners then summoned a conference of representatives of the Friendly Societies. Here the difficulties begin. The wishes of the societies are so far removed from those of the profession as to render a settlement satisfactory to both parties almost impossible. The profession lays down as a first principle of any scheme of certification that the certificate is to be that of the patient's own medical attendant, or, to put it more accurately, that the certificate of the member's medical attendant is to be regarded as *primâ facie* evidence of fitness or unfitness. The societies, on the other hand, or rather those who speak for them, are demanding that the entire certifying should be done by special whole-time officers. In other words, they suggest that what is required is an extension of the system which, established last summer, has succeeded in satisfying no one. The Commissioners have no easy task to reconcile these divergent ideals. The point forgotten by the societies is that the object of demanding a medical certificate is not to place obstacles in the way of members obtaining benefits to which they are entitled. That medical referees have been employed by certain societies in Ireland for this sole purpose is one of the gravest scandals which have arisen under the National Insurance Act. The true object of the medical certificate should be quite as much to secure his rights for the sick member without delay or difficulty as to safeguard the funds of the society. This is recognised by the more experienced societies, who also realise the futility of trying to carry on insurance work in a state of active hostility to the medical profession. In their present demands these saner societies seem to have been carried away by the heat of a few officials of the newer and less experienced societies.

Guardians and Medical Certificates.

At a recent meeting of the Edenderry board of guardians a resolution was carried to the effect that no medical officer acting as locum tenens for a colleague in case of illness should sign a medical certificate for such colleague. The circumstances which led to such an astonishing principle being laid down were simply that one of the medical officers, Mr. W. R. G. Hamilton, was ill, and that his illness had been certified by his colleague, Dr. J. J. Kinsella, who was doing duty for him. At the following meeting of the board a letter of protest against the insult contained in the resolution was received from all the medical officers of the union. It is satisfactory that a full apology was at once tendered, the board admitting that the resolution was unwarranted and had been passed without consideration.

Election of a Dispensary Medical Officer.

Extraordinary scenes took place at the election by the Westport guardians last week of a successor to the late Mr. J. J. McGreal, whose death from poisoning was recently recorded in the press. The board room was crowded with visitors interested in the election, including several clergymen, who, by permission, addressed the board in favour of the several candidates. All the candidates pledged themselves to be bound in their private practice by a scale of fees drawn up by the board.

Belfast Hospital for Sick Children.

At the forty-first annual meeting of the supporters of the Belfast Hospital for Sick Children held on Jan. 22nd it was reported that 585 (325 medical and 260 surgical) patients were treated in the wards during the year 1913, and 4622 (2383 medical, 1503 surgical, 595 eye, ear, throat and nose, and 141 dental) in the extern department. Forty-five senior students are attending the cliniques. To meet current expenditure there is in hand a sum of £492 7*s.* 4*d.*, and during the past year there was an excess of income over expenditure of £126 19*s.* 9*d.*, and £176 11*s.* have been invested.

Jan. 27th.

PARIS.

Anticholera Vaccine.

Professor Babès, of Bucharest, a former pupil of the French school, who always keeps his most interesting communications for Paris, recently reported to the Académie de Médecine his results in Roumania during the Balkan war with anticholera vaccination. He considers its value established, and that it may now take its place in current therapy. But as it is valuable more particularly as a preventive its action on the development of an epidemic can be established only when an entire community exposed to the disease has been vaccinated. As with antityphoid inoculation, its protection is complete only after at least two inoculations; one is not sufficient. There is a negative phase, during which the subject is more susceptible. The second vaccination should take place from six to eight days after the first. This also is followed by a very slight negative phase, but confers subsequently a stronger and more lasting immunity, the duration of which, however, is at present only a matter of conjecture. Bacillus carriers have been vaccinated without accident or reaction, but such vaccination does not appear to diminish the time during which the bacilli can inhabit the intestine. Moreover, M. Babès thinks that bacillus carriers, on a careful investigation, will be found to be less numerous than is thought, and that in the great majority of cases they do not retain the vibrios more than from 2 to 5 days. M. Babès has also made another interesting observation in the isolation camps—viz., that those who present the first symptoms of cholera do not show vibrios in their stools at the examinations made immediately preceding the symptoms. The incubation period of cholera, therefore, cannot be, as is commonly supposed, about 5 days, but only from 24 to 48 hours. As to the transmission of cholera germs by persons coming from infected regions, M. Babès holds that when they have left these regions for more than 14 days the transmission, if it occurs, is due neither to bacillus carriers nor to those incubating the disease, but rather to the conveyance of the germs on the clothing, linen, or in food. Prophylaxis, according to M. Babès, consists in early recognition and immediate and complete isolation of the first cases, with a rigorous disinfection and prompt vaccination of all contacts and the seeking out and isolation of germ carriers, not to mention the supervision of drinking water and the disinfection of fruit and vegetables. M. Babès insists that bacillus carriers do not constitute a very great danger, and that they are not found after the close of the epidemic. It is, therefore, hardly likely that it is by their means that an epidemic extinguished in the autumn breaks out again in the following spring. The vaccine can be prepared *en masse* when an epidemic threatens. M. Babès uses a large bottle holding from 1 to 4 litres, the internal surface of which is coated with a film of gelose. Twenty-four hours after insemination the bottle contains up to a litre of vaccine.

Comparative Statistics of Tuberculosis in the Precincts of Paris.

The Committee on Tuberculosis of the Conseil Général de la Seine has published comparative statistics of the mortality due to tuberculosis in 1896 and 1911 in the precincts of Paris. A comparison of deaths from tuberculosis with the general death-rate gives the following results. In the arrondissement of St. Denis in 1896 there were 1565 deaths due to tuberculosis out of a total of 10,615, or 14·7 per cent., as against 2939 from tuberculosis in 1911 out of a total of 15,558, or 18·9 per cent. In that of Sceaux in 1896 the tuberculosis deaths were 962 out of a total of 7850, or 12·33 per cent., as against tuberculosis 1692 deaths, out of 11,608, or 14·58 per cent., in 1911. The proportion of deaths from tuberculosis relatively to the number of inhabitants is as follows: St. Denis, in 1896, 332·4 deaths from tuberculosis per 100,000 inhabitants, the proportion rising in 1911 to 397·9. In Sceaux, in 1896, 297 deaths from tuberculosis per 100,000 inhabitants, the proportion rising in 1911 to 330·2. These figures show so rapid an increase of tl [illegible] Paris as to call for the [illegible] tuberculosis campaig [illegible] social causes whose influence remains inevitable, of which the chief is the influx into the capital of an increasing number of young people of both sexes who do not tolerate well the change of environment. This population, which comes especially from the poorer classes, herds together in overcrowded lodgings without the restraint of family ties, and becomes a speedy prey to alcoholism.

Jan. 27th.

SOUTH AFRICA.

The Position of the Nursing Profession in South Africa.

THE registration and examination of nurses and midwives in South Africa are at present in the hands of the Medical Councils of the different provinces constituting the Union. In the case of applicants holding certificates from other authorities registration is granted if the certificates are considered satisfactory. The requirements of the different councils in regard to local training vary considerably. In some cases the length of training extends from three to four years, according to the institution selected; in other cases certain institutions only are recognised, while institutions recognised by one council are not always recognised by another. The character of the examinations is uneven, and the tests do not adequately appraise the candidate's fitness for certification, much theoretical and but little practical knowledge of nursing being required. The general opinion by those in a position to judge is that the whole system requires thorough revision. This also seems to be the view of Government inspectors. In regard to nurses from overseas, certificates from other than large British hospitals are looked upon with suspicion as a rule, and recently several nurses, who have been trained in large continental hospitals, have been told that they must sit for examination if they desired registration. The value of trained nurses is being constantly recognised, and their position is improving year by year, the supply being considerably less than the demand. All the State-aided hospitals, other than those institutions which are able to undertake the training of probationers, have to employ temporarily numbers of unregistered nurses. It is probable that before long an attempt will be made to organise the nursing profession, which at present is without any recognised body to look after its interests, and already[1] a local nursing journal has been started. It is not unlikely that the Government may be induced to bring in legislation in the near future for the purpose of establishing a central nurses' and midwives' board in place of the four Medical Councils which have outlived their usefulness as registering authorities for nurses. The law, too, requires alteration in other respects, for, except perhaps in the matter of securing hospital appointments, it is no advantage for a nurse or midwife to be registered in South Africa. A number of locally trained nurses and the majority from overseas do not register, and find no difficulty in securing remunerative employment.

Dec. 28th, 1913.

---

[1] THE LANCET, Jan. 10th, 1914, p. 153.

A CENTENARIAN.—Miss Ritso, of Bath, celebrated her 102nd birthday on Jan. 26th. Her great-uncle, Dr. Grimm, was Court Physician to the Duke of Gotha. Her father, mother, and sister each lived to be nearly 100.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr J. A. Hirschl, assistant in the Vienna University Clinic for Mental and Nervous Diseases.—Dr. Wilhelm Bernoulli, of Basle, an eminent botanist, aged 75.—Dr. L. Kessler, extraordinary professor of gynæcology in the University of Iurieff (Dorpat).—Dr. P. Muselier, formerly physician to the Paris hospitals.—Dr. Giuseppe Cesari, professor of materia medica in the Modena Medical School.—Dr. G. Henry Torney, Director-General of the Medical Service of the United States Army.

A CORONER WHO HAS HELD 15,000 INQUESTS.—Mr. S. Brighouse, of Ormskirk, has just completed 30 years of service as coroner for the South-West Lancashire district, which includes Southport, Bootle, St. Helens, Widnes, and 77 other townships. Mr. Brighouse was appointed on Jan. 16th, 1884. During these 30 years he has conducted nearly 15,000 inquests, entailing over 180,000 miles' travelling by road, car, and rail. In the first year of his coronership nearly 500 inquests were conducted in public-houses; by 1913 the number had fallen to 80. Probably the most notable of the inquests conducted by him was that in connexion with the Maybrick case, which lasted several days and cost the country £265, the depositions extending to over 300 folios. The longest inquest held was in connexion with the Maypole disaster, which opened in August, 1908, and concluded in July, 1909.

Correspondence.

"Audi alteram partem."

TUBERCULOSIS DISPENSARIES IN LONDON.

To the Editor of THE LANCET.

SIR,—Recent occurrences have again brought before the profession the question of the public treatment of tuberculosis in the London area. After two years of consideration, perhaps too brief a period, a scheme has been evolved which represents approximately, if not the decision of the Local Government Board, at least a form of authoritative suggestion. It would appear from the wording of the document in which this is embodied that its inspiration is attributable in a considerable degree to the views expressed at a meeting of representatives of the twelve principal hospitals of the metropolis on Oct. 23rd, 1913.

The views of the public health departments have likewise received a full measure of attention. Proposals drawn up by the London County Council in a somewhat simplified form are practically identical in character. Local administration, including the immediate control of finance, is entrusted to the borough councils. General details of management, such as the keeping of statistical and other records, hardly call for comment at the present stage, but there are two principal considerations to which attention may profitably be directed. One is the relation of general hospitals to the dispensary system, the other the connexion with it of the public health department. At the meeting of hospital representatives decisions were arrived at on three points. 1. That it is important in the interest of the public and of medical education that general hospitals which are also medical schools should be utilised to the fullest extent in the treatment of tuberculosis in the London area. 2. That any local institution carrying out dispensary treatment shall refer special cases for consultative purposes to appointed hospitals. The hospitals named are: St. Bartholomew's, London Hospital, Guy's, St. Thomas's, University College, Charing Cross, St. George's, Westminster, King's College, St. Mary's, Middlesex, and the Royal Free Hospital. 3. That in addition to being recognised for consultative purposes, such institutions should, where they desire, also act as tuberculosis dispensaries, and in respect of such work should conform to the general conditions regulating dispensary treatment elsewhere. These conditions have been more or less completely incorporated both in the arrangements proposed by the Local Government Board and in those of the London County Council, the Board recommending that where a hospital is conveniently situated arrangements should be made enabling it to act as a local tuberculosis dispensary, while the County Council is prepared to deny approval to a dispensary which is not affiliated to a hospital to which special cases shall be referred for diagnosis or treatment. As regards the medical officer of health, while he continues doubtless to exercise the preventive and statistical duties of his own department as heretofore, it is provided by the Local Government Board that in the case of dispensaries established by the borough councils the medical officers of these dispensaries shall be attached to the staff of the public health department, and though they shall be independent in clinical matters they shall act under the administrative control of the medical officer of health, and further that visits from voluntary dispensaries shall be made under his direction. These restrictions apparently do not apply in the case of hospitals doing dispensary work. In addition there is provision made in the plan of the County Council for home visitation by the medical officer or his staff as well as by the tuberculosis officer in charge of the dispensary. It is thus apparent that the independence in clinical matters allowed to the medical officers of these institutions is of a strictly limited character.

Such in substance is the system approved at the present time by the Local Government Board and the Council for the County of London. That it is a genuine attempt to deal effectively with the treatment of tuberculosis there is no reason to doubt. It would be gratifying to find that it showed an equally clear perception of the bearings of the problem under consideration, and of the values and the relations of the forces available to deal with it and an equal judgment in coördinating them. Unfortunately this is not the case, for the proposed arrangement is lacking in some of the main factors of success. It accepts without reserve the propositions that have been set forth by the hospital representatives, which are at best of a one-sided character, and it is not too much to say that from this point of view the case has been overstated.

Recourse to hospitals is undoubtedly advantageous on many occasions, both for consultative and therapeutic purposes. This is particularly true in regard to tuberculous disease presenting difficulty or complexity, surgical tuberculosis, and advanced cases requiring treatment in bed. It applies probably more forcibly to specialised than to general hospitals, which are in comparison with institutions o the former class not much frequented by the tuberculous except for operative procedure. It mus also be recognised that the greater hospitals have educational requirements. They must have the means of supplementing theoretical study by clinica observation. All this may be freely admitted, but i does not necessarily follow that they are bes adapted to conduct tuberculosis dispensaries a part of their system.

There are conveniences, notably that of proximit to the homes of patients, which should be bette observed by the establishment of separate dispensaries in suitable situations in each borough area. A further and important consideration is the certain stimulus which institutions so placed would give to the efficiency of treatment carried out by local practitioners, on whose alertness and proficiency the extirpation, if that be possible, o tuberculosis must in the long run chiefly depend It is improbable that the hospital dispensary would prove equally useful in this respect. On the other hand, there should be no difficulty in providing the hospitals with those facilities for clinical teaching which they require, and it would be easy to associate the tuberculosis dispensary extramurally with the tuition of the medical school. This is done elsewhere in connexion with general medical treatment.

The position of the medical officer of health i the proposed system is even more open to criticism

He represents that section of the medical profession which has devoted itself to purely sanitary work. With clinical treatment, even in the preventive stage, he has no natural or proper concern, and, as a rule, but slight acquaintance. In view of this fact the statement that he and his staff will take part in home visitation requires to be explained. It can rightly apply only to the regulation of domestic surroundings. The examination of suspects and contacts belongs to the practitioner. There is the same sense of incompatibility when we find him empowered, apparently as a matter of routine, to direct visitation by the medical officers of the dispensary, who would presumably be competent men, while the clinical staff appears to be regarded merely as an appendage of the public health department. In truth the selection of the medical officer of health as the administrative head is in itself an anomalous proceeding which it is difficult to associate with normal ideas of proportion. All this executive elaboration makes for overlapping, confusion, misunderstanding, and friction. Smooth and efficient working would be better provided for by making the departments of treatment and sanitation independent while supplemental to each other, and by giving their officials distinct representation with a common responsibility to the local authority as the governing body.

There is one important omission in the scheme under examination—namely, the general practitioner. This is a serious error which, if not amended, cannot fail to prejudice the successful attainment of the objects aimed at. It can hardly be said that he has been definitely excluded. Except in so far as voluntary dispensaries with which he may be connected come under notice, he has been simply ignored. Yet he is the one man who in illness comes nearest with assistance, and who is and always will continue to be most relied upon by rich and poor alike. It is scarcely too much to say that if he remains true to his professional duty, which is probable, the future of medicine is in his hands. The significance of such a mistake as this is the more apparent when we reflect that the practitioner of the present day is a materially different type from his predecessor of the last generation. He has exact knowledge and scientific training, which he understands how to apply in practice. He also recognises in the treatment of tuberculosis, whether in the dispensary or in the home, an opportunity that falls legitimately within his sphere of action. His coöperation is under the circumstances essential to the success of any project for the treatment of this disease, and his abstention means its failure. To whatever misconception or default in counsel his omission is to be attributed, it can only be regarded as one proof the more that this scheme, in which he is not found, requires reconsideration.

I would briefly sum up the foregoing observations in these three propositions:—

1. That the tuberculosis dispensaries, while working in harmony with available hospitals, should be distinct from, not attached to them.

2. That public health departments should coöperate with, but not control, the dispensaries, the local authorities (borough councils), on which both are represented, being the governing bodies under the Local Government Board.

3. That duly qualified general practitioners should be eligible for all clinical offices connected with the dispensaries

I am, Sir, yours faithfully,

Islington, N., Jan. 27th, 1914. B. G. MORISON.

THE USE OF VACCINES IN PNEUMONIA.

To the Editor of THE LANCET.

SIR,—The prevalence of pneumonia at the present time makes Sir R. Douglas Powell's letter in THE LANCET of Jan. 24th of timely interest. It is to be hoped that those who have used vaccines in this disease will respond to his appeal for an expression of opinion. His own practice, of suggesting that a vaccine should be prepared from the sputum early in the attack, to be used in the event of continued severity or relapse of symptoms, and in some cases of slow resolution, probably represents that of most physicians. Vaccines are used as a last resort in cases doing badly.

My own practice is to regard every case as a possibly fatal one and to give a vaccine as early as possible after the onset of symptoms. Little immediate good can be expected when consolidation is present, for antibodies cannot penetrate into the solid airless lung. However, since all the lung is not in the same stage and parts may be in the condition antecedent to consolidation, good sometimes results. In the early stages of the disease before consolidation we are dealing with a septicæmia, and a vaccine then gives striking results. In a few cases I have been fortunate enough to give a vaccine within 24 hours of the initial rigor, in one case eight hours after the rigor. In these cases there has been an immediate response, and the after-course of the disease was profoundly modified. Usually the temperature fell to normal on the second or third day of the disease. In the case injected eight hours after the onset there was no further rise above 99·8° F., although consolidation occurred. Generally after the first fall the temperature rose again to a moderate height, and finally fell to normal after a second dose of vaccine. A recent case may be given as an illustration. A man, aged 46, had a severe rigor at 7 P.M. on Jan. 10th and his temperature rose to 105·2°. He was seen by me in consultation exactly 24 hours afterwards. His temperature then was 103·6°, respirations 32, pulse 116, rusty sputum, soft mitral systolic murmur. The only physical sign in the lungs was characteristic subdued breathing at both bases. His general condition was flabby, and we regarded him as a distinctly bad subject for pneumonia. A dose of 30 millions stock vaccine was given at once. At 6 o'clock the next morning the temperature was 100°, pulse 96, respirations 24. On Jan. 13th, 36 hours after the injection, the temperature was 98°, pulse 72, respirations 24. On the 14th the temperature rose again to 103°, pulse 108, respirations 40. Bronchial breathing was now present at both bases. A second dose of an autogenous vaccine containing 50 millions pneumococci and 50 millions micrococcus catarrhalis was now given. The temperature fell to normal next day and remained constantly normal. He was sent away to the seaside exactly 14 days after the initial rigor.

So striking have been the results when vaccine was injected early that I would urge the adoption of this practice. The amount of consolidation is probably determined by the events of the first few hours of toxic invasion, yet a consultant rarely sees a patient at this stage when so much could be done. It may be argued that if cases are injected early there is no proof that the cases really had acute *pneumonia*. But the sharp rigor, dry hot skin, rusty sputum, pulse and respiration ratio, and general appearance of the patients could scarcely be due to any other disease. It is an interesting point that in cases injected early *consolidation* may develop, although the temperature and pulse-rate are little above normal and the patients do not feel ill. The general symptoms improve out of proportion to the local disease. But it is unnecessary to wait for consolidation before making a diagnosis and giving a vaccine any more than one waits for the report on the throat swab before giving diphtheritic antitoxin.

If a vaccine is given at the commencement of the disease it must be a stock one. Owing to differences in strain it is advised that this should be a polyvalent vaccine. But the *difference* between strains is mainly one of virulence, and my own practice is to use a vaccine from a culture of high virulence. For some time I have been using one derived from a rapidly fatal case of pneumococcic meningitis. When possible I make an autogenous vaccine for each case, but I am not convinced that such a vaccine has any advantage over a stock vaccine from a virulent culture except when the infection is mixed. Many recent cases have shown the micrococcus catarrhalis, but even then one can assume that the pneumococcus is the predominant organism.

Unsuccessful results have been obtained by the use of inadequate doses. Doses of 5 to 10 millions are quite useless. My own doses have ranged from 25 to 50 millions, and with increasing experience I find myself inclining to the larger dose. I have not used more than 50 millions as an initial dose, but I now think that this dose may be too small to abort the disease, and that a still larger dose would give better results. Sir Almroth Wright has found small doses frequently repeated absolutely ineffective, and suggests that a dose of 500 millions might be tentatively employed at the outset of a pneumonia attack. The fear of a negative reaction has prevented many from using vaccines in pneumonia. I have never detected clinically any signs of a negative reaction after the doses I have used. Sir Almroth Wright, in connexion with his prophylactic inoculations, gives reasons for thinking that this stage may make default in the uninfected person and in the early stages of infection with doses of less than 1000 millions of a pneumococcic vaccine, which is with difficulty broken down in the body. If this fear can be abolished the way will be open for a more extensive use of vaccines in acute diseases.

Probably no physician has had a sufficient number of cases to furnish satisfactory statistical evidence, and such evidence as can be brought forward may fail to convince others who have not seen the cases which furnish it. But individual expressions of opinion may, I hope, encourage others to use vaccines promptly in this fatal disease.

I am, Sir, yours faithfully,

Birmingham, Jan. 25th, 1914. WILLIAM H. WYNN.

THE STERILISATION OF MILK AND ALLIED QUESTIONS.

To the Editor of THE LANCET.

SIR,—Dr. Eric Pritchard's letter in your last issue should suffice to dispose of Dr. Ralph Vincent's statement as to the "appalling effects" of feeding children on cooked milk; and I should not ask space for a few lines but for the reason that it occurs to me that your readers may be interested in an extract from a letter sent to me on August 6th, 1906, by the late Professor Budin—the founder (in 1892) of the present-day Consultations de Nourrissons, of which I believe there are at least 15 in Paris at the present time. Budin was a great clinician and a man who weighed his words most carefully; and his experience in the matter under dispute is of exceptional value, because at his Consultations children were kept under observation from birth until the age of 2. He writes that he made it his great concern always to give a carefully considered ("nettement déterminée") quantity of milk in order to avoid trouble; and writing after 15 years' experience he says, "Jusqu'ici je n'ai pas observé *un seul cas* de scorbut infantile." He maintains, with Variot and others, that it is the faulty amount and modification of the milk that give rise to such infant maladies, and not the cooking; and Budin found (as I have found upon inquiry in several cases brought to my notice) that in cases of alleged ill-effects from the use of cooked milk there have always been other factors to be reckoned with, which were, to say the least, quite as likely to have been responsible for the disturbance complained of. That the cooking of the general, 4*d.* per quart, milk-supply is a certain means of reducing the sum of sickness and mortality among the artificially fed infant population generally is conceded by all those who have tested the fact on a sufficient scale, although no one disputes that cooked milk, like breast milk, may prove unsuitable to occasional infants.

I am, Sir, yours faithfully,

HENRY KENWOOD.

University College, London, W.C., Jan. 27th, 1914.

To the Editor of THE LANCET.

SIR,—The letters by Dr. Ralph Vincent and Dr. Eric Pritchard in your last two numbers represent two opposing views on a question which is of extreme importance to all who are concerned with the feeding of infants. The paramount importance of breast-feeding is accepted by all, but, in spite of every effort to encourage breast-feeding, we are faced with the fact that under present conditions of civilisation there must always be a fairly large proportion of artificial feeding. Dr. Janet Lane-Claypon has shown in her report to the Local Government Board on the biological properties of milk, that breast-feeding, even if it is only for the first few weeks of life, is of extreme importance because it supplies the infant with those bodies which can only be secreted by, and absorbed from, an animal of the same species; she also says that the "biological substances" in raw cow's milk are not absorbed in the infant's alimentary canal but are destroyed there. If this is true, then one of the main contentions for the use of raw cow's milk is done away with. I wish to call the attention of all who are interested in this controversy to an important piece of work which they should read before they express an opinion.

If we consider, as most of us do, that raw milk is better for the infant than heated milk, we must add two important qualifications to our opinion: (1) That milk as delivered to the mother and given to the child shall be reasonably free from dangerous bacteria and their products, and (2) that the infant's digestion shall be able to cope with raw milk. For a milk to be reasonably free from bacteria, it should come from a herd free from tuberculosis, it should be efficiently cooled immediately after milking, and it should be kept cool until used for feeding. It is doubtful whether these conditions obtain at any but the model farms, and it is more than doubtful whether any of these model farms could supply milk at a price to place it within reach of the poorer classes of our large towns and still be worked at a profit. To those working in town areas this question of price is an all-important one. The second qualification is not so important, but there is no doubt that to many babies with impaired digestive powers heated milk is more digestible than raw milk, and at the same time that many infants who have to be fed artificially at an early age have from one reason or another impaired digestive powers when weaned.

Two other questions must also be answered: (1) Is there any danger of a baby contracting tuberculosis if it receives a certain number of tubercle bacilli of the bovine type from the cow's milk it takes? and (2) If there is such danger, is it better to use cow's milk heated at home by the mother or to use dried milk which has been sterilised soon after milking? The first question must be answered in the affirmative, and most emphatically so. The recent researches of Dr. Mitchell on cervical adenitis show that 90 per cent. of 72 consecutive cases were due to the bovine type of bacillus, whilst clinical experience in areas where tuberculosis is common leads one inevitably to the conclusion that tuberculous milk is responsible for a certain amount of the tuberculosis of early life. The fact that the amount of tuberculosis amongst cattle and amongst children varies in different localities may account for differences of opinion on this point.

If we think it advisable to avoid the danger of infection by bovine tuberculosis from raw milk we are forced to the conclusion that it is better to use heated milk. "Scalding" milk—a process that is similar to pasteurisation—does not apparently injure any of the chemical substances necessary to the health of the child. Therefore, if we consider that these chemical substances are necessary for the health of the child we should recommend scalding or pasteurisation of milk. Probably if the supply is reasonably pure this is the best thing to do. But if the milk is of doubtful age and cleanliness it is another matter, and we must consider the value of a full-cream dried milk. At the Manchester Schools for Mothers, at the Children's Hospital, and elsewhere I have watched a very large number of babies who have been fed on either scalded cow's milk or sterilised cow's milk or full-cream dried milk, and although I began with a prejudice against dried milk and expected to find a large proportion of rickets or scurvy amongst the babies so fed, I am bound to say that as a result of careful inquiry I am now of the opinion that dried milk gives better results than sterilised cow's milk, and I have no evidence that there is special advantage in using scalded milk. The question of the expense of dried milk as compared to scalded need not be discussed here, although it is, of course, of great practical importance. Further, at the Schools for Mothers it appears that not only are babies fed on dried milk less likely to develop diarrhœa in the summer than are babies fed on heated cow's milk, but also, what is more important, they are less liable to suffer from severe attacks of this disease. The fault lies in the present supply of raw milk, and it is bound to take time to overcome inertia and prejudice against new methods, to instal efficient apparatus, and to educate mothers up to the requisite standard. Most excellent work is being done by many public authorities to these ends, and any controversy that helps to further their efforts and to bring fresh evidence to light is of the greatest value.

I am, Sir, yours faithfully,

Manchester, Jan 26th, 1914. C. PAGET LAPAGE.

TREATMENT OF GASTRIC AND DUODENAL PERFORATION.

To the Editor of THE LANCET.

SIR,—In considering the treatment advocated by Mr. Edred Corner in his interesting paper published in THE LANCET of Jan. 10th, it is, I believe, very important to make a clear distinction between gastric and duodenal perforations.

Mr. Corner refers to two successfully treated gastric perforations, but implies that the treatment adopted in those cases is also applicable to perforated duodenal ulcers. This is, I think, a mistake; the possible results are quite different in the two groups of cases. In fact, the distinction is vital; a duodenal fistula practically never closes spontaneously, and the loss of the secretions which flow into the duodenum involves rapid death from inanition, while on the other hand a gastric fistula when not adherent to the abdominal wall tends to close rapidly, and the temporary escape of the gastric secretions on to the surface of the body, though possibly in some cases annoying and troublesome, is not of vital importance.

In certain cases during the past seven years I have from time to time employed a method somewhat similar to that which Mr. Corner recommends. The total number of gastric and duodenal perforations on which operation has been done is 35 with 8 deaths. This number includes 16 gastric cases with 3 deaths. Of the 16 gastric perforations, 10 were closed by suture and 6 were not sutured. In the 10 sutured cases there were 2 deaths; in the 6 unsutured cases there was 1 death. There is therefore a slight balance in favour of the unsutured cases. With regard to morbidity there is little to choose between the two groups. Subphrenic abscess developed in one of the unsutured cases and in two of the sutured cases. All three recovered after secondary transthoracic operation and long illnesses. In none of the unsutured cases was there any trouble from discharge of the gastric secretions; in some we could not be sure that there was any escape; in two only did evident leakage continue into the second week; in none was wound healing unduly prolonged.

I think it is important to point out, however, that the above applies only to one group of gastric ulcers—viz., those situated very high up on or close to the lesser curvature; all other gastric perforations were closely sutured. It is to be noted that one at least of the cases mentioned by Mr. Corner belongs to this group. In the earlier cases I anchored a drainage-tube, with a suture of No. 1 unchromicised catgut, close to the site of perforation and packed gauze loosely around the tube. In later cases I have eliminated the gauze altogether and simply used the tube, with no difference in the results and with avoidance of the trouble associated with removal of the gauze.

With regard to duodenal cases the situation is quite different; in 19 cases (duodenal and pyloric) there have been five deaths; in two cases the perforation was not closed and both patients died. One of these, a lad aged 18 years, was sent in three weeks after the onset of the illness with an abscess involving the whole right side of the abdomen from chest to thigh and pointing in the right iliac fossa. The abscess was incised, and pus, sloughs, bile, and curdled milk escaped; the cavity was found to extend far upwards. A second drainage incision was made in the loin; more bile-stained fluid and milk curd escaped; the source of leakage could not be found; the cavity was packed. The patient lived for some weeks, the fistula persisting and discharging intermittently. Death ultimately occurred from inanition. Post mortem the fistula was found to communicate with the second part of the duodenum.

The second case was that of a stout elderly man who had perforated eight hours previously. The perforation was found down in the second portion of the duodenum, and was brought within reach by incising and stripping up the peritoneum to the outer side of the viscus. The whole anterior wall of the second part of the duodenum was a thick, hard, œdematous plaque. The first linen suture cut out; the second did likewise. Two sutures of thick catgut were then passed through the whole thickness of the duodenal wall from side to side of the perforation and tied gently, approximating the margins of the opening simply edge to edge. A large drainage-tube was placed with its end in contact with the perforation and packed around with gauze. A gastro-enterostomy was not done because it appeared that owing to the situation of the lesion—i.e., opposite to or even below the level of the orifice of the bile and pancreatic ducts—an anastomosis would be likely to increase rather than diminish the risk of leakage. The patient rallied well and remained well until the third day, when duodenal fluids began to escape from the wound; the quantity of discharge—bile and pancreatic juice—steadily increased, till it became enormous. There were no symptoms of peritonitis. The patient died from inanition on the fifth day after operation.

I feel sure that any method (including omental plugging) which involves the possibility of a fistula, though sometimes useful in certain perforations on the gastric side of the pyloric sphincter, is very dangerous when employed in the treatment of a corresponding duodenal lesion.

I am, Sir, yours faithfully,

Middlesbrough, Jan. 25th, 1914. WM. S. DICKIE.

RESEARCH DEFENCE SOCIETY.

To the Editor of THE LANCET.

SIR,—By the death of its revered President, Sir David Gill, the Research Defence Society has suffered a very heavy loss. His death has come at the time when our society is just beginning the sixth year of its work, and we ask you kindly to publish this short note on the result of the past five years of work. We are of opinion that our society has helped to bring about a much better understanding of experiments on animals in this country. There is less of ignorance, prejudice, and ill-will; less readiness to accept without inquiry the charges made against this method of research; less doubt of its great value in physiology and pathology. The public is beginning to see that experiments on animals are useful in the maintenance of national health and efficiency, in the protection of men on foreign service, in the safeguarding of workers at dangerous trades, and in the immunising of live-stock against infectious diseases. It has come home to thoughtful people that diphtheria antitoxin, thyroid extract, salvarsan, amyl nitrite, and many other drugs, and many important facts in physiology, and the protective treatment against rabies, cholera, plague, Mediterranean fever, typhoid fever, tetanus, anthrax, and pleuro-pneumonia—to name these instances and no more—were discovered by the help of experiments on animals.

Of course, our society must not take more than its share of the credit for this advance of public opinion. Much of it is due to the labours of the Royal Commission, to the influence of the resolution passed last year by the International Medical Congress, and to the reverses sustained by our opponents. Moreover, the discoveries made of late years by medical research speak for themselves. Still, there is always need of interpreters of science to explain in simple words the advantages given to us by men of science for the saving or safeguarding not only of human lives but of animal lives. This work of popular interpreting is the especial duty of the Research Defence Society, and we look forward to many years of continued usefulness.

We remain, your obedient servants,
CROMER, Vice-President.
F. M. SANDWITH, Hon. Treasurer.
S. PAGET, Hon. Secretary.

21, Ladbroke-square, London, W., Jan. 27th, 1914.

THE DUCTLESS GLANDS.

To the Editor of THE LANCET.

SIR,—I have been very interested to read your section on Obstetrics and Gynæcology in the "Annus Medicus 1913" contained in your issue of Dec. 27th last. With the views put forward in your discussion of Dr. W. Blair Bell's lectures on the ductless glands and pelvic organs I am in entire accordance. It is indeed true that our knowledge of this subject as regards actual facts is very small, and it is also true as you state that "at the present time there is a widespread tendency to attribute all kinds of varying errors of metabolism to disturbances of one or other of the ductless glands when practically nothing is known with any certainty." You point out that Dr. Bell finds fault with Biedl because in his book there is no attempt to link up the connexions that exist between the ductless glands in regard to the specialised functions, and you express an opinion, with which I cordially agree, that Biedl has been right in refraining up to the present time from any such attempt. The facts at our disposal have so far not been sufficient to warrant us in drawing any very definite conclusions as to the interactions between the various organs furnishing an internal secretion.

Perhaps I may be allowed to point out that reviewers of my own book on internal secretion have in a similar manner complained that I have not dealt fully and definitely with this aspect of the subject. Thus, the *Universal Medical Record* says: "The broad conception of play and interplay between the various secretions, with the possibly balancing function of some of them, is nowhere given free expression." The reason for my hesitation to give "free expression" to this branch of the subject, as also presumably Biedl's reason, is admirably indicated in your own article, and amounts to a declaration that so far we have not had enough positive information from which to draw any general conclusions. I hope, however, in a future edition to make an attempt to correlate our knowledge on this branch of the subject, and any definite information which can be culled from the writings of Dr. Bell and other clinicians will be welcomed and incorporated.

I am, Sir, yours faithfully,
SWALE VINCENT.
University of Manitoba, Winnipeg, Jan. 6th, 1914.

DOSAGE AND THE METRIC SYSTEM.

To the Editor of THE LANCET.

SIR,—I have read with very much interest Dr. C. O. Hawthorne's able paper on Dosage in THE LANCET of Jan. 24th. With reference to his advocacy of the use of the metric system in dosage, I would inform both him and your readers that I have received an official notification from the General Medical Council that all measures in the next edition of the Pharmacopœia will be in the metric system, including those referring to dosage, but that in order to facilitate the use of the Pharmacopœia by medical men dosage will be given alternatively in the Imperial system also; the latter will be the only use of the Imperial weights and measures throughout the work. This procedure, which appears to meet Dr. Hawthorne's suggestions, has received in advance the approval of the pharmacists, and this association has taken the liberty of suggesting a similar procedure on the part of all those who are responsible for the preparation of unofficial pharmacopœias.

I am, Sir, yours faithfully,
G. E. M. JOHNSON,
Secretary, the Decimal Association.
Finsbury-court, Finsbury-pavement, E C, Jan. 26th, 1914.

A NATIONAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Though agreeing that the possibility for a patient to be attended by the doctor of his or her choice is of considerable value, I think it is putting the case too strongly to maintain that "the free choice of a doctor is the matter upon which everything turns." If it is of such importance, why is it that in the past the great majority of the population have been deprived of that right without protest? Why is it that even now it is denied to that most unfortunate section of society, the recipients of Poor-law relief? Their destitution, which brings them under the Poor-law, is generally the result of sickness, and it is of great importance to restore these patients to health as quickly as possible and so to make them once again self-supporting. Yet they are chained to a doctor selected for them by the guardians, and no insistent demand has been made by the profession to extend to them the right of "free choice," which just now is said to be of such great therapeutic value. The public has not been loud in its demand for this right, and the question arises whether the doctors' demand is purely altruistic and for their patients' good, or whether at the bottom there is not a feeling on the part of each individual doctor that he stands to gain.

You state that at the recent conference of Friendly Societies a proposal in favour of a State Medical Service was rejected by a substantial majority. This is true; but it was rejected in favour of the Friendly Societies' control of medical benefits, which would abolish the right of "free choice." The Scottish Clerks' Association proposed a resolution that steps should be taken to transfer the administration of medical benefits to the Approved Societies under the Insurance Act. As a direct amendment to this, Mr. T. W. Huntley, of Newcastle-on-Tyne, moved a resolution in favour of a State Medical Service, which was afterwards altered to "a full-time salaried medical service." This was lost by 89 to 16, and the original resolution was carried. A resolution standing in the name of Mr. George Cronin, of the Manchester Union, in favour of a State Service was then put and lost by 65 to 22. During the discussion no one pleaded for the present panel system with its free choice of doctor. The fight was for control by the Friendly Societies *versus* a State Medical Service, and of the two alternatives the great majority were in favour of the former. And the fight is not over; the Friendly Societies mean to gain control of the medical benefits and of the doctors if they possibly can. From the point of view of the medical profession there is nothing to be said in favour of the control of medical benefits by the Friendly Societies, but there would be many advantages in a State Medical Service, and as the trend of events is rapidly leading that way it would be wiser for the profession itself to prepare a scheme which would not be unacceptable to its members rather than allow a scheme prepared by Government lay officials to be thrust upon it. It would be possible under a State Medical Service to extend the possibilities of "free choice" to practically the whole population, and at the same time to do away with certain evils which are inherent to the necessity of catering for patients.

I am, Sir, yours faithfully,
CHARLES A. PARKER.
Upper Wimpole-street, W., Jan 26th, 1914.

THE NATIONAL INSURANCE ACT: THE SURPLUS FUNDS.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 10th, p. 149, you made some observations on a correspondence which has taken place with regard to the funds for medical remuneration retained by the London Insurance Committee. I should like to call attention to a point which has not been given due prominence in this correspondence.

The new agreements were signed, not in April, but before March 22nd, 1913, at which date we were still under the impression that an allocation of the residue would be made between April 1st and 14th, and Circular M.B. 9 of March 18th, which accompanied the agreements and directed their return before March 22nd, contains a reference to the coming allocation. It was not until the early days of April that we were informed that the allocation was postponed.

No medical man who is not in the habit of signing in blind faith unread documents would have signed that agreement accepting remuneration according to the schedule except on the understanding that an allocation would have been made by April 14th. The failure to make the allocation is no reason for repudiating the agreements; the worst that can be alleged against the committee is that their clerk was culpably optimistic as to the ability of his staff to cope with their enormous task, seeing that by the end of October they had only been able to trace about 40 per cent. of the insured who had chosen their medical attendants. But I think it is a valid reason for excluding from the operation of the schedule the remuneration due from those entitled to benefit before April 14th, 1913, who should have been allocated at that date. This view of the case is supported by the statement on p. 7 of that delightful pamphlet addressed to the profession by the Commissioners in December, 1912, which says that this method of calculating the remuneration will only apply "when the system is in full working." This pamphlet may not have the legal force of the Regulations, but at any rate shows the intentions of the Commissioners. Again, Circular 29 IC (*vide* The Lancet, Oct. 4th, 1913, p. 1032) recommending a distribution of unallotted persons quarter by quarter would also show that the Commissioners realised that remuneration according to the schedule would only be equitable provided there were no accumulated funds from the preceding quarters.

I certainly took Mr. Masterman's statement in the House of Commons on July 14th last to refer to this particular difficulty, and regarded it as an assurance that we should receive payment at the rate of 7*s.* a year for each of our acceptances during the year for whom 7*s.* was payable, though doubtless it also had reference to deductions for the Central Fund, about which the Commissioners were discreetly silent in the pamphlet of December, 1912. The Commissioners have made arrangements for us to receive full remuneration for the coming year, substituting the acquisition of powers of telepathy by the Panel Committee in place of the hard work previously demanded of the staff of the Insurance Committee, and I have no doubt will see that the remuneration for the past year is equitably divided amongst us.

Individual actions against the committee should be a last resort, but if all other means fail it is only fair that, if the committee were liable to be surcharged if they distributed our remuneration, they should also be liable as a surcharge to recompense any medical man who can prove that he has suffered loss through their neglect to make adequate provision for securing an allocation of the residue in April.

I am, Sir, yours faithfully,

Wells street, W., Jan. 19th, 1914. J. M. Twentyman.

To the Editor of The Lancet.

Sir,—Your legal correspondent says, in answer to my suggestion that a part at any rate of the unallotted insurance funds should be held in reserve for payment of doctors who, having gone to the aid of a midwife, are unable to get their fees from very poor patients, that "this hardly seems possible in view of the fact that the National Insurance Act, 1913, repeals the portion of Section 18 of the original Act, which permitted the fee of the medical practitioner in the circumstances indicated to be 'recoverable as part of the maternity benefit.'"

This repeal was made at the instance of the Midwives Institute, backed up by 55 affiliated associations of midwives in different parts of the country, for the wording of the old clause made it appear as if the societies would be responsible for the "recovery" of the doctor's fee as part of the maternity benefit, resulting in the societies holding back, in very many instances until the woman was up and about, the whole or part of the benefit from midwives' cases. This naturally prejudiced midwives and inflicted a great hardship on the poorest of insured persons, for whom the benefit was devised, and who most needed it during the puerperium. Your correspondent speaks of the *maternity benefit*, while I refer to unallotted funds for *medical benefit*—in my opinion two distinct things. These funds are no doubt still accumulating.

In considering my suggestion no one could say that the doctors would not be earning the money, which is a point raised by those who object to the whole unallotted funds being divided up amongst the doctors on the panel who have not been chosen by the insured people whose contributions are under consideration.

I am, Sir, yours faithfully,

Janet Ewart St. Clair,
Honorary Secretary, Fulham Association of Midwives.
Irene road, S.W., Jan. 25th, 1914.

⁂ Miss St. Clair is no doubt right as to the effect of the repealed section in practice; and the Insurance Commissioners would relieve poor women in childbirth from a difficulty which often presses hardly upon them if they could see their way to fall in with her suggestion.—Ed. L.

CHILLEY v. BRADFORD.

To the Editor of The Lancet.

Sir,—In the above case the jury held that a nurse was negligent because, on giving a sedative, she did not remove from the bed, or otherwise protect the patient from, a covered indiarubber hot-water bag, which had been placed there about an hour and a half previously, and with which the patient subsequently before his operation burnt himself.

The sedative in question I understand to have consisted of 1/6 grain of morphia and 1/120 grain of atropine given hypodermically, but, of course, the finding of the jury includes all sedatives and affects the ordinary practice and routine of hospitals, private or otherwise, and raises a question of some importance to the medical profession, as in the above case, though I was not held to have been personally negligent, I was held responsible for the alleged negligence of my nurse.

I am, Sir, yours faithfully,

Anthony Bradford, M.D. Durh.
Henrietta street, W., Jan. 24th, 1914.

⁂ The case is elsewhere dealt with.—Ed L

A CATALOGUE OF SUFFERING.

To the Editor of The Lancet.

Sir,—The system of election to the benefits of certain charities by a poll of subscribers has some obvious drawbacks as well as some advantages. One of the latter is the contact which it establishes between the subscribers and the nature of the work which is carried on by their money.

The Hospital for Incurables at Putney, for instance, sends out twice a year a voting paper, revealing an amount of human misery calculated to appal far more callous persons than those who subscribe to that splendid charity. Medically speaking, the column headed "Disease or Disability" is full of interest. At first sight it is surprising to find among the 192 candidates for the benefits of the society at the recent election not a single case diagnosed as malignant disease or as pulmonary tuberculosis. The explanation is probably to be found in the delay which necessarily ensues before a patient can be accepted; it always takes months, and generally years, to reach this much coveted haven of refuge, either as an in-patient or as a pensioner. Heart disease, again, is less prominent than might be expected; seven cases alone appear, and in most of them some other condition is superadded. Aneurysm and Bright's disease are absent from the list altogether. Turning to the common causes of disability, "rheumatoid arthritis" is diagnosed in 58 cases, and chronic rheumatism, osteo-arthritis, and rheumatic gout account for another 14—an eloquent proof of our therapeutic helplessness for these intractable disorders. The other main group is that of the paralyses, which includes at least 73 cases, and probably more. The diagnoses of these disorders are so confused that in the majority of cases it is impossible to identify the extent and nature of the disease. In a few cases disseminated sclerosis, locomotor ataxia, myelitis, and paralysis agitans are specified; but "paralysis" is the only label attached to the bulk of the cases. The point is of minor importance, no doubt, because most subscribers do not trouble themselves about the complaint of the candidate they vote for; but it does occasionally happen that a medical man is asked to advise upon the relative disabilities attaching to various diseases.

There are further instances of unsatisfactory diagnosis on the list. "Internal trouble" appears two or three times; not, by the way, from a false delicacy, for "fibrous tumours" are specified in another case. "Debility after surgical operation" may be a euphemism for something more tangible, especially as the candidate is in her sixth year of application; but it is ambiguous and therefore objectionable. Graves's disease as a qualification for an incurables' charity may be a slight shock both to some physicians and to some surgeons. "Creeping paralysis" is a curious phrase in a list presumably derived from medical certificates, and "nervous debility" is equally vague and meaningless. Hæmophilia, myxœdema, and anæmia with enlarged spleen are some of the more uncommon and interesting diagnoses put forward. Doubtless the investigations of the society's officers exclude all except really urgent and deserving cases; but there is room for improvement in the system of setting forth the diagnosis and in the information thereby supplied to the electors.

I am, Sir, yours faithfully,

Jan. 17th, 1914. M.D. CANTAB.

THE NATIONAL INSURANCE ACT.

PENALTIES FOR ARREARS OF CONTRIBUTIONS.

AT a joint meeting of the Insurance Advisory Committees for England, Scotland, Wales, and Ireland draft regulations were considered fixing penalties for those falling into arrears with their contributions. The scheme proposed by the Commissioners was submitted by their actuary, Mr. A. W. Watson, and was unanimously approved. At the end of each contribution year—i.e., in June—each member's net arrears, if any, are to be ascertained, certain credit allowances being made, and he is to have the opportunity of paying them off before Oct. 1st. If on that date he is still behindhand the arrears then found will be his "penalty arrears" for the benefit year beginning Nov. 1st, and reductions of his benefit will follow upon a scale depending upon the number of payments which he has failed to make, and having as its extreme penalty the suspension of all benefits for one year. This is to take place when the penalty arrears exceed 26.

THE INSURANCE MEDICAL SERVICE IN LONDON.

It was noted at the meeting of the London Insurance Committee on Jan. 22nd that in the case of practitioners who have accepted service on the panel for a limited number of persons the clause will be omitted from the agreements which states that doctors will treat persons who have been assigned to them by the committee. It was decided to issue a circular letter to the medical profession emphasising this point, Dr. H. H. Mills (chairman of the Medical Benefit Subcommittee) remarking that a fear of having patients assigned to them had prevented many doctors from coming on the panel. There were about 1000 doctors whose practices were amongst the insured classes who had so far remained outside the Act, and it would be advantageous if a proportion of them could be attracted to the panel. On a motion by Dr. Mills, seconded by Dr. B. A. Richmond, the Medical Benefit Subcommittee was instructed to report as to the sufficiency of the arrangements for medical benefit in the various boroughs of London. Allusion was made to the criticisms of the panel service made by Sir John Collie, and noted in the last issue of THE LANCET (p. 280). Mr. F. Coysh (chairman of the General Purposes Subcommittee) observed that too much general abuse of the panel system had been indulged in upon the committee. The time had come for practical suggestions for its improvement. Some criticism was also passed upon waiting-room and lavatory accommodation at surgeries in East London. The committee passed a further resolution instructing a subcommittee to report as to the adoption of a scheme for the nursing of insured persons.

INSTITUTIONAL TREATMENT OF TUBERCULOSIS IN LONDON.

The cost of institutional treatment of tuberculosis in the metropolis appears, from a report presented to the London Insurance Committee on Jan. 22nd, to have been considerably increased by the decision of the London County Council to rely chiefly upon such temporary accommodation as the Metropolitan Asylums Board could provide. The rate per head works out at 40s. 2½d., against the more usual 30s elsewhere. Restricted accommodation prevents the reception of a sufficient number of cases to effect more economical working. The Insurance Committee, whilst fully appreciating the assistance of the Metropolitan Asylums Board (but for whose readiness in emergency institutional treatment would be almost a dead letter in London), has pointed out to the London County Council the unsatisfactory and expensive nature of the present temporary arrangements, and has urged the importance of securing permanent accommodation at an early date. At the same meeting of the Insurance Committee a resolution was passed expressing regret that the County Council had let slip the opportunity of acquiring for tuberculosis treatment the Mount Vernon Hospital, Hampstead, which has now been purchased by the Medical Research Committee formed under the Insurance Act. Mr. D. E. Warburg, a prominent member of the County Council, in defending the inaction of that body, made the announcement that in regard to the treatment of tuberculosis the Council adopts the same attitude as in the case of medical treatment of school children—namely, of dependence upon voluntary organisations.

ASSOCIATION OF INSURANCE COMMITTEES IN WALES.

A conference of representatives of Insurance Committees in Wales and Monmouthshire was held recently at Shrewsbury for the purpose of forming an association of the Welsh Committees. Speeches expressing satisfaction at the working of the Act were made, and the following statements with regard to its operation were made among others. Weekly payments in respect of benefits amounted to £7500; £6000 were spent weekly on medical benefit and £1700 on maternity benefit. There were 966 medical men and 668 chemists on the panels. £8000 had been received for mileage allowance. Persons living more than three miles from any medical man had been noted, and it was reasonable that account should be taken of the nature of the country to be traversed. As to sanatorium benefit, there had been but three institutions dealing with tuberculosis in Wales in 1911, but now there was a network of them, with the result that already 796 patients had received treatment in sanatoriums and 1018 in hospitals, 9241 having been treated or recommended for treatment at institutes and visiting stations.

UNALLOTTED FUNDS AT CROYDON.

The Croydon Insurance Committee has decided to allocate the fund in its hands, arising from 10,000 insured persons not having selected a medical man on the panel, in the following manner. One-half to be divided among all the practitioners on the panel in proportion to the number of patients on the list of each, the other half equally between them. The medical men in return are to undertake to treat any of the insured persons who have thus failed to make their choice and who may come to them, after which the name of any such patient is to be placed according to circumstances on the list of a medical man.

CHEMISTS' GRIEVANCES IN MANCHESTER.

It appears that the Manchester chemists are very indignant as to the way they have been dealt with since the coming into force of the National Insurance Act, which they did their best to further by cheerful and willing coöperation. There seems to have been what is called "over-prescribing" by some medical practitioners, and the drug fund does not seem to meet all the expenditure of the chemists, who have not so far received payment in full for the prescriptions made up by them. In Salford there are 109 medical practitioners and 52 chemists on the list of the Salford Committee. Up to Dec. 14th, 1913, the chemists' claims amounted to £11,194. The drug money available for the period at 2*s.* a head was £7516, which works out at a little over 66 per cent. of the amounts claimed.

TORONTO GENERAL HOSPITAL.—The Private Patients' Pavilion of the Toronto General Hospital was opened on Jan. 6th by his honour Sir John Gibson, the Lieutenant-Governor of Ontario. This marks the completion of the Toronto General Hospital, which has been erected at a cost of £700,000. The out-patients' pavilion, which has been luxuriously furnished, cost £71,800 to construct and £10,000 to equip. The charges will range from about £3 3*s.* to £20 a week. The foundation-stone of the new hospital was laid on April 11th, 1911, by Earl Grey.

Medical News.

UNIVERSITY OF OXFORD.—The following medical degrees have been conferred :—

B.M.—C. W. Wheeler-Bennett, Christ Church; and R. S. A. Heathcote and W. W. Waller, New College.

UNIVERSITY OF CAMBRIDGE.—The following medical degrees have been conferred :—

M.D.—A. J. Clark, King's; and A. C. D. Firth, Trinity.

M.B. and B.C.—F. S. Tinker, Pembroke; and D. S. Bryan-Brown, Downing.

B.C.—J. Deighton, Trinity; A. G. G. Thompson, Pembroke; W. Boys-Stones, Caius; and J. Brewer, Emmanuel.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—E. M. D. N. Baker (Sections I. and II.), Brussels; J. C Gillies (Sections I. and II.), Leeds; T. H. W. Idris (Sections I. and II.), University College Hospital; and S. de Moor (Section II.), D. Schonken (Section II.), and J. D. Schonken (Section II.), Amsterdam.

Medicine.—C. Bluett (Section I.), London Hospital; E. S. Dufty (Sections I. and II.), Sheffield; J. C. Gillies (Sections I. and II.), Leeds; G. B. Holroyde (Sections I. and II.), London Hospital; S. de Moor (Sections I. and II.), Amsterdam; J. A. Prendergast (Sections I. and II.), Leeds; E. Renouf (Sections I. and II.), Royal Free Hospital; J. D. Schonken (Section I.), Amsterdam; and J. A. Watson (Sections I. and II.), London Hospital.

Forensic Medicine.—E. M. D. N. Baker, Brussels; E S. Dufty, Sheffield; J. C. Gillies, Leeds; S. de Moor, Amsterdam; J. A. Prendergast, Leeds; and E. Renouf, Royal Free Hospital.

Midwifery.—E S. Dufty, Sheffield.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. M. D. N. Baker, T. H. W. Idris, S. de Moor, J. A. Prendergast, and D. Schonken.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co., Limited, announce for immediate publication "Surgical Diseases and Injuries of the Genito-Urinary Organs," by Mr. Thomson Walker.

MEDICAL BARRISTERS.—The following medical practitioners were called to the Bar on Jan. 26th: Inner Temple, Dr. W. H. L. McCarthy; Middle Temple, Dr. Robert Scott and Mr. H. C. Waldo.

THE PROVISION FOR TUBERCULOSIS TREATMENT IN LONDON.—The Metropolitan Asylums Board on Jan. 24th devoted further consideration to the question of provision in London for treatment of tuberculosis. Pending the receipt of a complete statement from the London County Council of the accommodation required, the Local Government Board had intimated that it was very desirable that further immediate provision, if only of a temporary nature, should be made for hospital cases. To meet this request the General Purposes Committee proposed to take a lease of a receiving home for children in Milman-street, Chelsea, from the Westminster board of guardians. There would be accommodation for 50 patients, and the cost per head was estimated at 35*s.* a week. The present arrangements at the Downs Sanatorium, proceeded the committee, were quite insufficient to allow of adequate classification of patients, and hospital cases were being received as well as cases for which the institution was opened. Except for the beds which the Insurance Committee had been able to engage in private sanatoriums London had no suitable open-air sanatorium available for early cases most needing and most likely to repay institutional care and treatment, and in this respect the metropolis was far behind some of the Home Counties, which had made considerable advance towards the provision of new sanatoriums. The Asylums Board, of course, was not a free agent in this matter and could make no progress in it, even by agreement with the Insurance Committee, without the concurrence of the County Council. The present temporary and unsatisfactory arrangements came to an end in March, and would have to be extended unless a permanent and comprehensive scheme were entered into by that time. Having regard to the need for a modern and up-to-date open-air sanatorium for early cases, the General Purposes Committee considered that the Asylums Board should take the preliminary steps towards such provision without waiting for the final settlement of all the principles involved. Until the County Council had settled questions connected with the treatment of other classes such an institution as proposed would be limited to insured persons. A communication should be sent to the County Council asking it to approve, as a temporary measure, of an agreement being made with the Insurance Committee for this purpose The Board approved both these proposals of the committee.

SANITARY AFFAIRS AT ILFORD.—From the published reports of the last meeting of the Ilford district council, held on Jan 27th, it appears that the council refuses to follow the advice of the Local Government Board to reconsider the dismissal of Mr. C. F. Stovin, medical officer of health On the previous evening a meeting of the townspeople of Ilford passed a resolution asking the council to remove Mr. Stovin's suspension, and similar resolutions have been carried by the local Ratepayers' Association This matter was dealt with in THE LANCET of Jan. 17th, p. 199.

A MEDICAL VETERAN.—Mr. Philip Whitcombe, the oldest medical man in England, died on Saturday last, Jan. 24th. He qualified in 1838 as M.R.C S. Eng., later taking the diploma of the Society of Apothecaries, and was the first medical officer appointed for the Port of London at Gravesend His family have for many years been medical practitioners at Cleobury Mortimer, and he was a freeman of Salop by descent, his ancestors dating their freedom since 1423 One of his sons is Dr. P Percival Whitcombe, and another is the present Bishop of Colchester Mr. Philip Whitcombe's memory at the age of nearly 98 was unimpaired, and he did a certain amount of professional work as recently as ten years ago, and could read without glasses until the age of 92. Truly a medical veteran.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN ROYAL HOSPITAL FOR SICK CHILDREN.—Female Superintendent

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL —House Surgeon, unmarried Salary £100 per annum, with board, washing, and lodging

BANBURY, HORTON INFIRMARY —House Surgeon Salary £100 per annum, with board and residence

BIRKENHEAD BOROUGH HOSPITAL —Senior House Surgeon and Junior House Surgeon Salary £120 and £100 per annum respectively, with board and laundry.

BIRKENHEAD UNION —Senior Resident Assistant Medical Officer. Sala[illegible]

BIRMING[illegible] Path[illegible]

BRADFO[illegible] Salar[illegible]

BRENTF[illegible] W — [illegible] £150 per annum.

BURNLEY, VICTORIA HOSPITAL.—Second House Surgeon for six months. Salary at rate of £80 per annum, with residence, board, and washing

CALCUTTA, CORPORATION OF —Two District Health Officers Salary Rs 500 per month each, and all allowances

Canterbury, Kent County Asylum, Chartham.—Junior Assistant (Third) Medical Officer, unmarried. Salary £220 per annum, with apartments, attendance, laundry, &c.

Cardiff, King Edward VII.'s Hospital.—House Physician and House Surgeon for six months. Salary at rate of £60 per annum each, with board, residence, and laundry.

Carmarthen, Joint Counties Asylum.—Second Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, &c.

Chester, County Asylum.—Third Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, and washing.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board and washing. Also Honorary Radiographer. Also Physician to Out-patients.

Colchester, Essex County Hospital.—House Physician. Salary £100 per annum, with board, residence, and washing.

Darenth Industrial Colony for the Feeble-minded, Dartford, Kent.—Third Assistant Medical Officer, unmarried. Salary £180 per annum, with board, lodging, and washing

Derby County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Doncaster Royal Infirmary and Dispensary.—Assistant House Surgeon. Salary £100 per annum, with board, apartments, and washing.

Dorchester, County Asylum.—Third Assistant Medical Officer. Salary £250 per annum, with board, lodging, &c.

Dorchester, Dorset County Hospital.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and laundry.

Durham County Council.—Assistant Tuberculosis Medical Officer. Salary £300 per annum.

Durham County Asylum.—Third and Fourth Assistant Medical Officers, unmarried. Salary £200 per annum, with board, lodging, and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—House Physician and Assistant Casualty Officer for six months. Salary at rate of £75 per annum, with board, residence, laundry, &c.

East Suffolk, Administrative County of.—Assistant to County Medical Officer of Health. Salary £300 per annum.

East Sussex County Asylum, Hellingly.—Third Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, washing, and attendance.

French Hospital and Dispensary, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £60 per annum, with board and laundry.

Glasgow District Mental Hospital, Lenzie.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, attendance, and laundry.

Gloucester, Barnwood House Hospital for Mental Diseases.—Second Assistant Medical Officer. Salary £200 per annum, with board, &c.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

Hampstead General and North-West London Hospital.—Assistant Casualty Officer for Out-patient Department, Bayham-street. Salary at rate of £60 per annum, with board, residence, and laundry.

Hospital for Sick Children, Great Ormond-street, W.C.—House Physician and House Surgeon, unmarried, for six months. Salary £30 each, with board and residence, &c. Also Surgeon Dentist.

Hospital for Women, Soho-square, W.—Clinical Assistants in Out-patients Department.

Huddersfield, County Borough of.—Assistant School Medical Officer. Salary £300 per annum.

Isle of Ely, Administrative County of.—Assistan Medical Officer of Health. Salary at rate of £350 per annum.

Kensington Dispensary and Children's Hospital.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

Leeds General Infirmary.—Resident Aura Officer and Resident Obstetric Officer. Salary £100 and £50 per annum respectively, with board, residence, and laundry. Also House Physician for six months. Board, residence, and laundry provided.

Liverpool City Infectious Diseases Hospital.—Two Assistant Resident Medical Officers, unmarried. Salary £150 per annum, with board, washing, and lodging.

London Homœopathic Hospital, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Assistant Physician. Also Assistant Surgeon for Diseases of the Eye. Also Assistant Gynæcological Physician.

London Temperance Hospital, Hampstead-road, N.W.—Resident Medical Officer. Salary £200 per annum, with board, residence, and washing. Also Assistant Resident Medical Officer for six months. Salary at rate of £40 for six months, with board, residence, and washing.

Maidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £200 per annum, with quarters, attendance, washing, &c.

Manchester Royal Infirmary.—Accident-room House Surgeon for six months. Salary £100 per annum, with board and residence. Also Assistant Medical Officer, unmarried, to Convalescent Hospital, Cheadle, for six months. Salary at rate of £80 per annum, with board and residence.

Manchester Township Workhouse, Crumpsall.—Junior Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with rations, apartments, washing, attendance, &c.

Middlesex Hospital, W.—Director of Institute of Pathology. Salary £800 per annum.

Newcastle-upon-Tyne, Hospital for Sick Children.—Honorary Physician.

Newport (Mon.), Royal Gwent Hospital.—Resident Medical Officer. Salary at rate of £100 per annum, with board, residence, and laundry.

Nottingham, City of.—Assistant Medical Officer, unmarried, for Bagthorpe Institution and Infirmary, for six months. Salary at rate of £165 per annum, with apartments, &c.

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £180 per annum, with apartments, &c.

Nottingham, Ransom Sanatorium, Sherwood Forest, Mansfield.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

Paddington Infirmary.—Assistant Medical Superintendent of Infirmary and Medical Officer of Workhouse. Salary at rate of £170 per annum, with board, lodging, and washing.

Perth District Asylum.—Assistant Physician. Salary £150 per annum and all found.

Plymouth, South Devon and East Cornwall Hospital.—Surgeon Dentist.

Preston, County Asylum, Whittingham.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, and washing.

Preston Royal Infirmary.—House Physician. Salary £100 per annum, with board, residence, and laundry.

Reading, Royal Berkshire Hospital.—Second House Surgeon. Salary at rate of £80 per annum, with lodging, board, and laundry.

Rochester, St. Bartholomew's Hospital.—Resident House Physician. Salary at rate of £110 per annum, with board, residence, and laundry.

Royal Naval Medical Service.—Twenty-five Appointments.

Ryde, Royal Isle of Wight County Hospital.—Resident House Surgeon, unmarried. Salary £125 per annum.

St. Austell Union and Rural District Council and Workhouse.—Medical Officer. Salary £400 per annum for combined appointment.

Scarborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with board, residence, &c. Also Junior House Surgeon. Salary £80 per annum, with board, residence, &c.

Sheffield City Education Committee.—Assistant School Medical Officer. Salary £300 per annum.

Shrewsbury, County Asylum.—Senior Assistant Medical Officer and Second Assistant Medical Officer, unmarried. Salary £250 and £200 per annum respectively, with board, apartments, laundry, attendance, &c.

Southwark, Metropolitan Borough of.—Tuberculosis Officer. Salary £500 per annum.

Straits Settlements Government.—Three Medical Officers. Salary £300 per annum.

Sunderland Royal Infirmary.—House Physician. Salary £120 per annum, with board, residence, and laundry.

Swansea General and Eye Hospital.—House Physician. Salary £125 per annum, with board, apartments, and laundry.

Tadcaster, Goole, Riccall, and Selby Rural Districts and Selby Urban District.—Medical Officer of Health. Salary £500 per annum.

Tooting Bec Asylum, Tooting, S.W.—Third Assistant Medical Officer, unmarried. Salary £180 per annum, with board, lodging, and washing.

Warrington, Lancashire County Asylum, Winwick.—Pathologist and Assistant Medical Officer, unmarried. Salary £250 per annum, with [illegible] washing.

Warwick Count [illegible] —Second Assistant Medical Offic [illegible] nnum, with board, lodging, and laundry.

West Bromwich and District Hospital.—Assistant Resident House Surgeon and Anæsthetist, unmarried. Salary £75 per annum, with board, residence, and washing.

West Ham and Eastern General Hospital, Stratford.—Junior House Physician. Salary at rate of £75 per annum, with board, residence, and washing.

West Ham, County Borough of, Temporary Sanatorium, Dagenham, Essex.—Resident Medical Officer, unmarried. Salary at rate of £300 per annum, with apartments, board, and washing.

Winchester, Royal Hampshire County Hospital.—House Physician. Salary £80 per annum.

York County Hospital.—House Physician for six months. Salary at rate of £100 per annum, with board, residence, &c.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Arnesby, in the county of Leicester; at Ballyward, in the county of Down; at Midleton, in the county of Cork; and at New Ross, in the county of Wexford.

*** The summary of vacant appointments, published weekly in this column, is, equally with other articles, the literary copyright of the Proprietors of The Lancet.

Births, Marriages, and Deaths.

BIRTHS.

Bruce.—On Jan. 27th, at 72a, East Dulwich-grove, S.E., the wife of H. W. Bruce, M.D., F.R.C.S., of a daughter.

Dick.—On Jan. 24th, at Roxeth, The Glebe, Blackheath, the wife of F. A. Dick, M.B., B.S., of a daughter.

Higgs.—On Jan. 21st, at Palace Mansions, Kensington, the wife of Frederick W. Higgs, M.D., of a daughter.

Manby.—On Jan. 25th, at Victoria-street, Westminster, to Dr. and Mrs. E. P. Manby, a son.

MARRIAGES.

Wood—Keir.—On Jan. 20th, at St. Marylebone Presbyterian Church, W., Stanley Wood, M.R.C.S., L.R.C.P., to Mary Robb Keir, of Laurieston, Falkirk.

DEATHS.

Whitcombe.—On Jan. 24th, at Gravesend, Philip Whitcombe, M.R.C.S., in his 98th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PAPER CLOTHING.

D[illegible] ent years several newspapers [illegible] paper as a chest protector to [illegible] well as flannel but with less bulk." This is a debatable matter, but there is no doubt about the utility of paper as clothing. Paper is no new substance for clothing, and has been in use amongst the Chinese and Japanese for a long time. Japanese and Chinese ladies are accustomed to underclothing made of a tough silky paper, and European ladies have worn sets of the same material, although difference of climate and custom have precluded the spread of the fashion, and perhaps also the inferior quality of the paper supplied to [illegible] years ago during a very hot [illegible] n attempt to spread its use, [illegible] fashion also. Paper is the successor to parchment (membrana) or vellum, and those to the papyrus or paper reed. But brown paper, the first kind to be manufactured in any quantity in this country, is without doubt the best for retaining heat. A sheet of brown paper heated by the fire and folded a few times and put into a pocket near the body is like a pocket stove A sheet may be inserted between the lining and cloth of a waistcoat or thin coat. A sheet folded and cut to the shape of the feet is a useful addition in bad weather for those who wear thin boots [illegible]

AN OBJECTIONABLE SOLICITATION.

To the Editor of THE LANCET.

SIR,—A London firm of opticians has a branch in the city [illegible] mine [illegible] A few [illegible] name [illegible] ing it [illegible]

> Jan. 13th, 1914 —Dear Sir,—Upon looking through our books we find that it is now over two years since you last consulted Dr. ———. As with sight like yours it is always desirable to have the eyes periodically examined, we take the liberty of calling your attention to the matter, in case the lapse of time may have been unnoticed by you We are, Sir, yours respectfully,

Disapproving such action I called on the manager and learned that he had written about 30 letters of the kind since the beginning of the year, referring to different ophthalmic surgeons, and that the head establishment in London has been in the habit of doing this for some years past He [illegible] se [illegible] ne [illegible] en [illegible] ns [illegible]

KING'S COLLEGE HOSPITAL.

THE *Hospital Gazette* for January is devoted to an illustrated description of the new King's College Hospital at Denmark Hill. First comes a detailed architectural description, with *plans and many half-tone pictures* This is followed by a description of the engineering plant similarly illustrated, and a brief article on the drainage, water supply, and fire main. The price of the issue is 1s. 3*d*., including postage All those interested in hospital construction will find useful information in this detailed account, showing how problems have been solved and difficulties overcome in the construction of this institution

A PISTOL PIPE

EVERYBODY has read or heard stories of burglars and other intruders being frightened aw[illegible] tobacco pipe in lieu of a pis[illegible] casting of a shadow on the bli[illegible] tobacco pipe may in reality [illegible] An assistant master at an Essex school was recently [illegible] n an explosion occurred, [illegible] of the stem and entered [illegible] as hurt, otherwise the [illegible] ubject of an interesting medico-legal inquiry. The smoker's explanation is that shortly before the explosion he had been to the miniature rifle range and had practised shooting. He assumes that a live cartridge in his pocket lodged by accident in the pipe and that after he had filled the bowl and had been smoking for a few minutes the burning tobacco fired the cartridge.

"A MUSEUM OF SANITARY DEFECTS"

AT the last meeting of the Holsworthy (Devon) urban district council the medical officer of health in reporting some cottages as uninhabitable stated that the Local Government Board inspector had recently referred to them as a "museum of sanitary defects"

THE COMPLIMENTARY DINNER TO DR. ADDISON.

Dr. H. H Mills asks us to state that this dinner has been unavoidably postponed until Friday, Feb. 6th. It will be held at the Hôtel Metropole, London, at 7.30. Reception from 7 to 7 30.

Th[illegible] en received:— [illegible] Bulletin of the [illegible] al of Obstetrics [illegible] iew of Reviews [illegible] orge's Hospital [illegible] del Uruguay, [illegible] Gynæcology of [illegible] w, Archives of [illegible] tology, Annales [illegible] al, Archiv für [illegible] South African Medical Record bones on dead people to ensure technical skill, we should see and hear far less than we now do of operative failures.

For the past three years I have been pursuing these two lines of investigation, mending fractures which I have made in the bones of living animals and dead men. For my present purpose I propose to show typical examples of the experimental work, so as to give the basis of the various principles in the operative treatment of fractures, referring those interested in the matter, to a recent publication[1] for a full account of my work on animals.

RESULTS OF OPERATIVE FIXATION IN ANIMALS.

Most of my animal experiments have been on cats, a few only being on rabbits, using chiefly the tibia and sometimes the femur. No attempt at external splinting was made, the animals being allowed to use the limb according to their own instinct.

On Insecure Fixation.

One of the greatest surprises that my experiments afforded me was the demonstration of what a relatively strong fixation was necessary to keep the ends of a broken bone in good apposition until they had firmly grown together. The tibia of a cat is about 1/4 inch thick, and its medullary cavity measures about 1/8 inch. If this bone is divided and then a solid bone peg inserted into the marrow cavity, although this is one-half the original thickness of the bone, it was invariably broken, and the same thing occurred in the femur, where the peg used was 5/32 inch thick. This fracture of the peg did not occur at once, the muscles remaining somewhat inert for a few days after the traumatism of the operation, but at about 5 to 7 days after, when the animal first began to use its limb. The fixation must leave the bone as strong as it was before the fracture, or there will be a risk of its speedy breakage.

The use of short plates fixed by small screws, which hold only by their bite of the dense bone, gives similar results. In such cases I have never seen a fracture of the plate, but the screws become loosened from one or both ends of the bone. (Fig. 1.) Bone is a living tissue, and as such it softens and yields before local pressure. The words of Sir William Macewen are pertinent in this connexion. He says: "A pin driven into the diaphysis, so that it is firmly caught, will in the course of a few days become loose, owing to the softening which the mechanical stimulation has set up in its periphery. The greater the pressure the greater the area of softening."[2] Obviously the same thing applies to tightly driven screws.

This fact is of great importance when we have regard to the prevalence of screwing methods in modern bone surgery. A screw which presses upon the bone will rapidly loosen its hold; the rapidity with which it becomes loose will be in direct proportion to the pressure which is exerted upon it. This loosening of screws which fix plates to bones may be minimised in two ways, either by using a large number of screws, so that the pressure upon any one is small, or by keeping the limb rigidly splinted so that muscular traction is reduced to a minimum. By either of these devices the plate may hold in place until vital union has occurred, but it is clear that such a result will be rather a happy accident than a certain effect.

The objection may be raised against my experimental methods that the plates were so short that they cannot be compared with those used in human surgery. But in the first place the question of size is a relative one. The plates were about one-fifth the length of the bone, which would be equivalent to a 3-inch plate used for the human tibia or femur. The screws were one-eighth of the thickness of the shaft, which would give screws 1/8 or 3/16 inch thick for the human leg bones. And, secondly, the inefficient principle of the method, depending as it does upon the fact that every tightly driven screw becomes loose by reason of its own pressure upon the bone, will not be altered by any increase in the size or number of screws, though by this means its ill effects may be averted.

Whatever may be the cause of the insecurity of fixation, the results are extremely bad—i.e., every possible variety of mal-union or non-union, with the frequent addition of septic complications. An operative fixation of a fracture, which gives way early, leaves the bone in a very much worse condition than it was before the operation. And this for at least four reasons: (1) that in the course of the operation the periosteum and muscular sheath of the bone have been separated from it to some extent, and therefore the preventive of displacement is lost; (2) there has been some interference with the minute vascular supply of the bone ends; (3) there is a loose foreign body left in the tissues; and (4) there is an external wound through which sepsis is very likely to enter.

On Incomplete Fixation.

There are some methods which are perfectly efficient as regards the strength of the union they produce, but they allow from the outset some slight movement between the bone ends.

The most important among these is the application of encircling wire under certain conditions. I have not studied this systematically by experiment, because the use of wire having been so largely abandoned in human surgery there did not seem to be much practical use in the research. But I have often used it in addition to such things as gelatin or decalcified pegs. These pegs are very quickly broken or absorbed, and the obliquely divided bone, left surrounded by several turns of wire in very much the same way as fractures used to be treated by "wiring." Such a union is always bad. The bones cannot slip altogether apart, but the divided ends are constantly chafing against the wire. This chafing occurs just at the very place from which the principal agent of repair, the external callus, originates. The early stage of callus consists of soft granulation tissue, and this will be destroyed by the rubbing wire just as fast as it is formed. Hence I always found in my experiments that the most certain means of preventing or delaying bone union will be by the loose encirclement of the broken ends by wire.

Another method which allows slight mobility of the fragments without displacement is that of intramedullary pegs. These can only be slipped into the bone ends if they fit rather loosely. The result on the healing of the bone in this case is the tendency to the production of some amount of callus excess. This will occur especially in the case of single bones, such as the femur or humerus, where the peg does nothing to prevent rotation of the fragments. (Fig. 2.) I have never seen any harm as regards the function of the limb arise from this callus excess either in animals or human beings, but it is not a desirable condition, especially as one has no means of controlling it. But, nevertheless, the uniformly good results, the facility of its application, and the small incision through which it can be applied, make the method one of great value, which I shall speak of again when dealing with human fractures.

---

[2] Growth of Bone, p. 21.

On Mechanically Efficient Fixation.

In the course of upwards of 100 experiments upon animals the fact which has impressed itself upon my mind more than anything else is the importance of mechanical efficiency of fixation. A broken bone is a part of an ever-moving piece of machinery, of which the surrounding muscles form an integral portion. Even if voluntary movement be abolished by external splints there is always the strong tonic contraction of the muscles to be reckoned with.

It is like mending the broken shaft of the propeller of a steamer. For a short time the engine is at rest, but the broken shaft in that time must be so fixed together as to withstand all the throbbing of the engine and the beating of the seas until the ship can reach her harbour. So with an operation on a broken bone under the anæsthetic the ever-pulling muscles are quiet, and during that moment, *if the surgeon is to do any good*, he must so fix together the bone that it can withstand any strain likely to be put upon it until natural repair has taken place. Of course, this analogy must not be pushed too far, for the bone will heal if left to nature, while the steam engine will not. But nature has her own method, and if the bone is completely broken the ends become displaced and the limb shortened, so that the muscles are thrown out of gear, and the condition of stable equilibrium or rest demanded for reparative processes is thus attained, but often at the ultimate expense of the length and form of the limb.

If a long plate be applied to a bone, and fixed by pins or screws which go through its whole thickness and are not held by a mere frictional grip, but by a relatively broad flange or nut, then there is provided a mechanically efficient union, and such union has in my experiments given uniformly good results. (Fig 3.) Generally I employed what are technically termed split or cotter pins, fixing a steel plate about one-third of the length of the bone. I have also used double plates, on opposite sides of the bone, joined through its thickness either by cotter pins or by bolts and nuts. Ten such experiments without a single failure have convinced me that the principle is correct, and it only remains to master the technical difficulties of its application.

Firm, strong bone union occurs without any callus excess, showing that absolute fixation of the fragments is no hindrance to vital repair. The animals use the leg freely from a week to a fortnight after the operation, showing that no splints and no after-treatment are necessary to secure a functionally perfect result.

The Problem of Sepsis.

From the earliest days of the operative treatment of fractures the problem of sepsis has largely dominated the question. At first it seemed to be flying in the face of Providence to convert a closed into an open fracture. And then it became a common experience, and possibly is so to the present day, for the post-operative course to be complicated by the occurrence of a septic sinus, which only closed when the metal substances used for the operation had been removed. Hence the dictum that asepsis is the first and chief necessity for fracture operations. That asepsis is the first necessity no one would deny, but asepsis during the operation by no means ensures that no septic complications shall afterwards arise.

First let me give my experimental evidence of this before I attempt to explain it. In a long series of cases where the bones were not firmly or properly fixed (short plates and screws or pegs which broke or were absorbed) there was a very high proportion of sepsis, amounting to about 60 per cent. In an equally long series where the bones were firmly united there was not a single septic case.

Now such a result in the hands of the same operator, and under the same conditions, must prove that there is something else than a fault of aseptic operating. And this other or post-operative factor is not far to seek. When the bone is united in such a way that disunion occurs, the fragments moved by the muscles cause a great outpouring of lymph, and the foreign bodies lying loose in the tissues produce the same result. This fluid quickly oozes out from the recent wound, and along the sinus thus formed, sepsis quickly finds its way from the skin to the deep tissues, where there is every encouragement for its development. Exactly the same thing happens in human surgery. A wobbly union of the fragments or loose screws, especially if these lie just beneath the skin, cause a discharge, which becomes septic. This is one or two weeks after the operation, and it is the result and not the cause of the faulty fixation.

The Question of Delayed Union.

This is another point of great importance. Is there any evidence that operative treatment *per se* causes this? Experimentally as well as clinically I think there is. Clearly one can only deal with this point in cases uncomplicated by any other untoward event. In the two methods which have given uniformly good anatomical and functional results—viz., those with the long plates and transfixing pins and the steel intramedullary pegs—I have had one instance of delayed union in each series.

I do not think it is due to mere immobility, otherwise it would occur as the rule, and not as the exception, when the bones are rigidly fixed. It is caused, I think, by an interference with the blood-supply of the bone ends by the operative manipulations. This causes the cut ends of the bone to remain inert for a time, and unable to throw out any reparative callus. But in both cases where I have observed it, the delayed union did not cause any evidence of its presence—that is to say, the function of the limb was perfect, and I have no doubt that if the animal had been kept alive long enough (both were killed at a period of six weeks after the operation) union would have eventually taken place.

We must admit, I think, that delayed union is a possible result of operative fixation, but this will leave little or no ill-effect if the fixation has been so efficient as to last for an indefinite time.

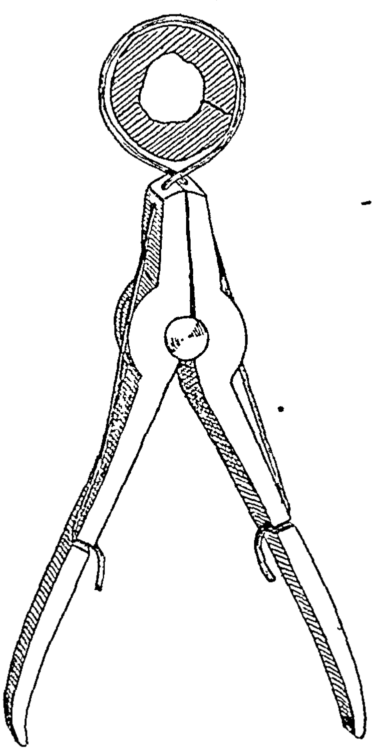
On Indirect Methods of Fixation.

It is possible to hold firmly the ends of a broken bone in good position without directly interfering with the site of a fracture. I did this by transfixing the bone as far as possible from its point of division and connecting the transfixing rods by outside metal bars. Such a method accurately and certainly carries out what many of the more precise of the

Wire made of aluminium-bronze and of plated copper is in some ways a good material, but the copper is a powerful irritant poison in the tissues, which makes me disinclined to use it in either of these forms. In experiments where bronze wire has been used there is always an area of green discolouration in the tissues all round it, caused by the action of the copper. Soft iron wire is far superior to silver. It is much stronger than either bronze or silver. For example, samples of No. 24 (standard wire gauge) of silver, aluminium-bronze, and iron wires had a breaking strain of 31 lb., 44 lb., and 50 lb. respectively, as tested in the engineering laboratory. It is, of course, very cheap and can be obtained tin-plated.

The second point of importance in using wire in bone surgery is that the fragments must be accurately restored to proper position, or at any rate to a stable equilibrium, before the wire is tightened. This is often very difficult to do. The parts are often brought into approximate position and then the wire placed as tightly as possible, or actually used as a traction material. Then when the muscles begin to act, the badly fitted bone ends become loose, and there is just that loose surrounding with wire which I have above shown to be so inimical to fracture repair.

FIG. 6.



Forceps for tightening and twisting wire when the bone suture has to be done in the depths of a wound.

Again, there is a third error commonly made in the use of wire. It is tightened by being twisted. This always makes a weak place in the wire at the junction of the last twist with the circular piece, and here the wire often breaks. It is absolutely necessary that the wire be drawn tight so as to allow no movement whatever, and when this has been done a single turn should be taken without relaxing the tension, and after the long ends have been cut off three further turns are taken in the short ends without any tension at all. This manipulation has often to be carried out in the depth of the soft tissues, and it is advisable to have some mechanical contrivance, such as the forceps I have devised, to carry it out. (Fig. 6.) The principle of these wire-tightening forceps is that the wire ends are caught in the blades, which open when the handles are pressed together; and a force, which is five times as great as the hand tension used, is applied to the tightening of the wire in exactly the right plane. Then by a single twist of the handles of the forceps the first twist is made, and the forceps can be disconnected whilst the extra-safety twists are given and the ends cut off and turned down.

If used under the conditions laid down—i.e., strong material, accurate reposition of the fragments before tightening, and firm tightening before twisting, I believe that wire will serve a purpose in a very restricted number of fractures, which cannot be equalled by any other method. The three cases in which it is especially indicated are fractures of the olecranon and patella and very oblique fractures of long bones where it is difficult to make a complete exposure without serious injury of the soft parts.

In the case of the patella it is most important that the wire should be applied in the form of a single circle which surrounds the circumference of the disc without any kinking. It is a mistake to make the suturing in a vertical plane, because the boring of the patella in this is difficult to do accurately, the wires hold chiefly in the loose cancellous tissue of the bone, and the wires become sharply kinked when tightened and the fragments tilted.

On the Usual Methods of Plating Fractures.

The common method of operative fixation of fractures is the screwing of linear steel plates upon the outer surface of the bone by means of short screws which only hold to the dense bone on one side of the marrow cavity. In spite of the fact that the method in the hands of Sir Arbuthnot Lane has achieved such success that it has become the standard of operative treatment, I would venture to point out the several ways in which it falls short of the ideal of mechanical efficiency to which I think we ought to aim.

I have already given the reasons derived from experiments for saying that the screws, however tightly they are inserted, will become loose within a short time. There is abundant evidence that this is so, too, in clinical practice. In some cases the screws come out before any union has occurred and a gross displacement, worse than that which would have taken place without any operation, results. I have seen this repeatedly, but especially in cases of the upper third of the femur. In other cases the screws hold long enough for union to occur, but nevertheless eventually become loose in the soft tissues and necessitate a further operation for their removal. The insecurity of this method of fixation is admitted by its advocates by their practice of putting up the limb after operation on splints for periods of from four to eight weeks, so that no strain shall be placed upon a lightly joined bone. Such an after-treatment subjects the limb to all the evils of immobilisation that have been so amply demonstrated by Bardenheuer, Lucas-Championnière, and many others. It risks all the disability consequent upon adherent tendons and stiff joints.

Consider for a moment the mechanical conditions of a femur plated in its middle third by a plate 4 inches long with three screws on each side of the fracture, each screw being 1/8 inch thick and holding in 1/4 inch thickness of dense bone. For the moment let us think of the bone as merely non-vital material. All the screws are in the same line, and therefore the bone, 1 inch thick and 16 inches long, has to be held by the grip of the plate upon a part of its own substance which is 1/4 inch thick, 4 inches long, and 1/8 inch wide. However strong the plate the total strength of the union cannot be greater than that of the piece of bone to which the plate is fixed. The actual width of this piece of bone is only 1/25th of the circumference of the tubular structure of the shaft, and therefore only 1/25th of the strength of the bone can be restored by the use of this method.

Then there is the fact that soon the screws become loose. This disadvantage it is sought to counteract by using many screws. But as all these are in the same line the chief stress must fall upon those nearest the fracture, as will be seen by the accompanying diagram. (Fig. 7.) When there is any force tending to bend the bone in the direction of the arrows the plate, unless very massive, will bend slightly, and all the stress will fall first upon the screws A and B and then upon C and D and so on.

FIG. 7.

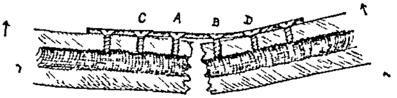


Diagram showing how a long linear plate with short screws becomes loose. However many screws are placed in the [illegible] displacing force acting in the direction of the

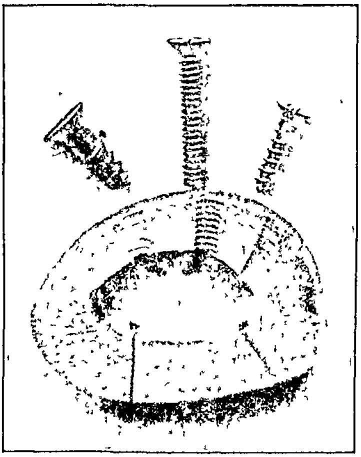
Therefore, for all these reasons the linear plating of fractures can only be regarded as a very temporary and insecure union of the bones, which can only succeed if (1) rapid vital union occurs, (2) splints are kept rigidly applied until union has taken place, and (3) that the part be one, such as the lower leg, which can be controlled and immobilised by splints.

One further point of some importance requires mention, and that is the very great superiority of the "metal-threaded" over the "wooden-threaded" screws. (Fig. 8.) This, I think, was first pointed out by Lambotte, of Antwerp, and has been more recently insisted upon by various American surgeons, notably by Sherman and Gerster, but nevertheless the wood screw remains in almost universal use in this country.

The wood screw is intended to bury its thread in the substance of yielding wood, but it cannot do this in a dense bone. A metal screw, on the other hand, must have a female screw thread tapped for its reception, and this is most readily done by some sort of a cutting arrangement at the end of the screw itself. By this means the screw, instead of merely holding by the frictional grip of the very edge of its thread upon the bone, has its whole thread uniformly embedded in the bone, and its grip will thereby be enormously increased in strength. The metal screw holds because it fits into a socket made for it, whilst the wood screw holds in dense bone by the sheer pressure of the edge of its thread upon the hard wall of its socket. Lambotte, by using these metal threaded screws and by not hesitating to perforate the bone, so as to hold it by both sides, has greatly improved the plating method, so as to dispense with the use of the splint in the after-treatment. But even though this firmer and longer fixation of screws improves the method, it does not do away with the objection that the whole strength of the union cannot be greater than the thickness of bone engaged by the single line of screws.

FIG. 8.



A piece of bone into which three screws have been driven. Note the slight grip of the "wood" screws as compared with that of the "metal" screw.

So far I have only referred to the dense structure of the bone shafts. If we consider the structure of the ends of the bone where there is only a very thin shell of dense tissue and all the rest is spongy substance, it is evident that such parts will afford no hold at all for screws.

(To be concluded.)

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Jan. 27th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward. The patient suffering from abdominal pains and a temperature of 104° F., the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E 20 (4) Not carrying [illegible] or antiseptics required by R[illegible] ance upon a patient and t[illegible] patient who was suffering from puerperal fever and not undergoing disinfection to the satisfaction of the local supervising authority as required by Rule E 5. Not wearing a clean dress of washable material when attending a patient, as required by Rule E 1.; neglecting to adopt the antiseptic precautions prescribed by Rules E 3 and 7; not keeping the register of cases, as required by Rule E 23, and medical aid having been sought the midwife neglected to send any notification thereof to the local supervising authority, as required by Rule E 21 (1).

SOME COMMON ERRORS IN THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE JOINTS.[1]

BY ARTHUR P. LUFF, M.D., B.SC. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL.

THE *differentiation* of diseases of the joints is not always an easy matter. It certainly requires a considerable amount of experience, and it is therefore not surprising that errors in the diagnosis of diseases of the joints, and consequently in their treatment, are of fairly frequent occurrence. I propose to deal in this lecture with most of the common errors that are apt to occur, and I shall place them in the order in which they have been met with in my experience, commencing with the most frequent errors and gradually proceeding to those which are of comparatively rare occurrence. As errors in the diagnosis and treatment of surgical diseases of the joints will be dealt with in another lecture at this College, I do not propose to refer to acute synovitis, acute suppurative arthritis, tuberculous disease of joints, or syphilitic disease of joints.

1. *Differential diagnosis of rheumatoid arthritis and gout.*—The confusion of these two diseases of the joints in their chronic forms is, in my experience, one of the commonest errors. Of all the forms of chronic joint disease they are the most frequently met with, and therefore are the most apt to be confounded. The differential diagnosis of these diseases is a very important matter, because undoubtedly in the past many cases of rheumatoid arthritis have escaped recognition and have been diagnosed as gout. When it is considered that the treatment of these two diseases is quite different, the necessity of a correct diagnosis is manifest.

The following distinguishing characters show how very different the two diseases are. In the first place, rheumatoid arthritis occurs most commonly in females; gout occurs mostly in males. Rheumatoid arthritis occurs more commonly amongst the poor and ill-nourished; gout mostly among the well-to-do and well-nourished. Rheumatoid arthritis is a disease which is improved by good dieting; in the case of a gouty person a spare and plain diet is indicated. The onset of rheumatoid arthritis is insidious; that of gout sudden and obvious. As regards the commencement of the attack, gout most commonly begins in one of the feet, especially in the great toe joint; rheumatoid arthritis, although ultimately it frequently affects many joints of both hands, nearly always begins in one joint, most commonly selecting one of the joints of the thumb, either the carpo-metacarpal or metacarpo-phalangeal joint, after which it rapidly spreads to the other joints. Then as regards the appearance: in the case of rheumatoid arthritis there is no obvious swelling at first and no marked redness, while in the case of gout at its commencement there is very obvious swelling, marked redness, and a shiny condition of the skin around the affected joint.

In rheumatoid arthritis there is very little pain at first. There is some aching in the joint, but it starts in a very insidious manner. It is this insidious character of the disease which is one of its bad features, for the patients do not seek advice until the affection is fairly advanced. Gout, however, begins in the most marked manner with severe pain, the patient as a rule waking up in the early morning with excruciating pain in the great toe. Therefore if there is doubt as to whether a particular case is one of rheumatoid arthritis or of gout the patient should be questioned as to the commencement of the attack in order to ascertain whether it began with an obvious outburst of pain and with swelling and redness of the joint, or whether it began very insidiously. Then as to the joint affections; apart from what has been stated as to gout generally beginning in the foot and rheumatoid arthritis in the hand, there is one joint commonly affected in rheumatoid arthritis which is not affected in cases of gout—viz., the temporo-maxillary articulation. I have never seen a case of gout in which the temporo-maxillary joint has been affected, whereas in rheumatoid arthritis it is fairly common for that joint to be affected.

In rheumatoid arthritis there is a special liability to the affection of the joints of the cervical vertebræ, as evidenced by pain and stiffness at the back of the neck. This is a most useful distinguishing sign. Another distinction is this, and it is perhaps one of the most important distinctions, that in connexion with rheumatoid arthritis there is a remarkable symmetry in the affection of the smaller joints of the hands. In gout that symmetry is wanting. Lastly, in a case of rheumatoid arthritis sodium biurate is neither found in the joints nor in the blood, whereas in the gouty person sodium biurate exists both in the joints and in the blood.

The not infrequent mistake of diagnosing rheumatoid arthritis as gout, and the consequent placing of the patient on a restricted and spare diet, has undoubtedly led to the development of severe and incurable forms of the disease. It is essentially a disease that requires good and nutritious feeding, and I have seen many cases of rheumatoid arthritis which have gone thoroughly to the bad through the initial error of mistaking the disease for gout and treating it with a spare diet.

2. *Differential diagnosis of chronic rheumatism from rheumatoid arthritis and gout.*—I am sure that many cases which are diagnosed as chronic rheumatism of the joints are not chronic rheumatism at all; many of them are cases of rheumatoid arthritis and a fair number are cases of gout. Though much less frequent than is generally supposed, chronic rheumatic affections of the joints do occur, but they never produce that excessive permanent deformity which the other affections may. These chronic rheumatic affections of the joints are generally accompanied by the formation of fibrous nodules, by the development of extra-articular fibrous thickening, and not infrequently by the indication of valvular disease of the heart. There is generally a well-marked history of rheumatism, and the disease is identical with that described as "chronic fibrous rheumatism." It must not be considered that the subcutaneous fibrous nodules occur only in connexion with rheumatism. They are fairly frequently seen in cases of rheumatoid arthritis, and less frequently in gout, syphilis, influenza, and other diseases.

It should be carefully remembered that chronic rheumatism is not associated with the formation of bony or cartilaginous deposits in the joints. It shows little symmetry, and is usually associated with rheumatic pains shifting about from one place to another. It never affects the temporo-maxillary joints. As regards the actual diagnosis of rheumatism, it is usually fairly easy. If a patient complains of pain in the joints, which pain flies about from joint to joint and generally affects some of the muscles at the same time, and if, in connexion with these flying pains, there are indications of the presence of the rheumatic erythema—erythema nodosum—then the diagnosis of rheumatism is obvious. As a rule, the fitful way in which the joints are affected, the fairly rapid subsidence of the swellings of the joints, and the association of muscular pains make the diagnosis a simple matter. The absence of bony thickening and of bony grating distinguishes the disease from rheumatoid arthritis, and in addition the finger-joints are much less frequently affected.

---

[1] Founded on a lecture delivered at the Medical Graduates' College and Polyclinic on Feb. 11th, 1914.

As an assistance in the diagnosis of a chronic articular affection there is a rough but fairly sure test which is frequently of assistance: it is treatment with salicylate of soda. If the case responds well to this treatment it is a case of rheumatism. If it does not respond to this treatment the existence of rheumatoid arthritis or gout is fairly certain, as neither of these affections responds well to salicylates.

Chronic fibrositis of the joints is most frequently met with in the knuckle and finger-joints of those engaged in hard manual labour, especially when associated with damp surroundings. Pads upon the finger-joints constitute a chronic form of localised fibrositis. They form excrescences which are almost confined to the dorsal aspects of the interphalangeal joints of the proximal row, and are only very rarely seen upon the terminal joints of the fingers. They are usually present upon the fingers of both hands, and vary in size from that of a split-pea to that of the half of a hazel-nut. Sometimes they are quite painless, but more often pain of various degrees of severity is complained of, especially when the fingers are flexed or if the lumps are knocked. Patients suffering from these pads generally seek medical advice under the apprehension that they are the precursors or accompaniments of rheumatoid arthritis, or that they are due to chronic gout. There does not, however, appear to be any connexion between these pads and either rheumatoid arthritis or gout. There is, however, an intimate connexion between these pads and Dupuytren's contraction of the palmar fascia, and it is fairly common to see the two conditions together.

3. *Differential diagnosis of acute rheumatoid arthritis and acute rheumatism.*—In its early stages acute rheumatoid arthritis may very closely simulate acute rheumatism, but it may be distinguished from it by not reacting to treatment with salicylates. The disease usually commences in one joint, commonly one of the metacarpophalangeal articulations, and then rapidly spreads to other joints. The disease does not flit from joint to joint as in cases of acute rheumatism, and the joint swellings are persistent. The swelling is at first due to peri-articular thickening rather than to effusion. Rapid muscular wasting, vaso-motor troubles, and pigmentation occur. In the acute and subacute stages the temperature is raised, but as a rule is lower than in acute rheumatism.

4. *Differential diagnosis of acute rheumatism and acute gout.*—As a rule these two diseases in their acute forms can be readily distinguished, but in cases of doubt the question can be settled by attention to the following points. The colour of the affected joints is usually quite different, being of a dusky-red or purple-red colour in acute gout, and of a pale rose pink in acute rheumatism. Acute gout as a rule only starts in one joint, whereas in acute rheumatism several joints are simultaneously affected. The pain of the affected joint in acute gout is much more severe than in acute rheumatism, especially when the joint is touched or handled. The swelling of the joint is usually much greater in acute gout than in acute rheumatism. The sweating in cases of acute gout is slight in comparison with the profuse sour-smelling perspiration of acute rheumatism.

5. *Differential diagnosis of chronic villous synovitis from arthritis and displaced cartilage.*—In my experience it is a very common error to mistake a chronic villous synovitis, usually of one or both knees, for an arthritis. Chronic villous synovitis is a purely local condition and not a manifestation of a general disease. It is, unfortunately, described in some text-books as "arthritis sicca." It usually occurs in the knee, and is characterised by crepitus or creaking on movement and by pain and tenderness on use. The crepitus during movement of the joint is frequently unpleasantly audible to the patient, and is especially caused by going up or down stairs. The capsule and the ligaments of the joint are more or less relaxed and the synovial membrane is passively congested and loose. The crepitation on movement is due to the folds of the flabby congested membrane rubbing together—in other words, it is a true creaking and not a bony grating. If further relaxation of the synovial membrane results, hernial-like projections of the synovial fringe may be produced which are apt to cause a catching or locking of the joint when it is moved. In this class of cases the fluid in the joint is generally quite normal, although, if there be great irritation, some excess of it may form. The condition is very frequently mistaken for rheumatoid arthritis, but there is no erosion of cartilage and no eburnation of the ends of the bones, consequently bony grating can never be produced in such joints.

A valuable aid to the recognition of this condition and to its differentiation from rheumatoid arthritis is the careful auscultation of the joint. The knee-joint should be slowly flexed and extended during the examination, and in this way the peculiar crackle or crepitus that is produced by the thickened and flabby synovial membrane is easily distinguished from the scrunch or grating sound that occurs in cases of rheumatoid arthritis, and which is due to abrasion or erosion of the cartilages.

In a few cases of chronic villous synovitis of the knees the hypertrophied fringes, as the result of chronic inflammation, act as foreign bodies, and their removal may be necessary to effect a cure. Many cases of so-called displaced cartilage in the knee-joint are due to the nipping of these hypertrophied and protruding fringes.

6. *Differential diagnosis of subacromial bursitis and arthritis of the shoulder-joint.*—The confusion of these two conditions is a fairly common error. In both cases the pain is complained of in, or in the vicinity of, the shoulder-joint, and in both cases a marked sound may be elicited on movement of the joint. The condition of the bursa is one of a chronic fibrositis, which may occur in any of the bursæ, but is especially apt to occur in connexion with the subacromial bursa, which is the same as the so-called subdeltoid bursa. The other bursæ which exist about the shoulder-joint are relatively

the joints from osteo-arthritis.—The arthropathy known as Charcot's joint is occasionally mistaken for an osteo-arthritis, but the association of it with locomotor ataxy, the rapid effusion, the usually rapid destruction of the cartilages and bones, and the remarkable absence of pain should prevent such an error in diagnosis.

Queen Anne-street, W.

MITRAL STENOSIS, CARDIAC THROMBOSIS, AORTIC EMBOLISM, AND GANGRENE OF BOTH LEGS.

BY H. E. SYMES-THOMPSON, M.A., M.D. CANTAB., M.R.C.P. LOND.,

PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL; ASSISTANT PHYSICIAN TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE following case is interesting, not only because it is unusual, but also owing to the difficulty which it presented in the diagnosis of the underlying cause. The embolus measured 1¼ inches by ½ inch, and it lodged at the bifurcation of the aorta, being too large to enter one of the common iliac arteries. The diameters of the common iliac and the common carotid arteries are ½ inch and ⅓ inch respectively; and we usually regard an embolus which plugs one of these vessels, causing unilateral gangrene or sudden death, as a large embolus. The embolus in this case was therefore of exceptional dimensions. The diagnosis of mitral stenosis could not be established during life. There was some irregularity of the heart, but nothing else on which to found such a diagnosis could be made out; and there was no history of rheumatism. The thickening and tortuosity of the arteries suggested the possibility of syphilitic endarteritis, but the Wassermann test gave a negative result. The absence of sugar from the urine excluded diabetic gangrene.

The patient, a man aged 47, was admitted to the Great Northern Central Hospital on Feb. 5th, 1913, complaining of discoloration of the legs accompanied by pain and loss of power. The illness had begun 14 days previously, when pain came on suddenly in the legs. The pain was like pins and needles, was worse at night, and was marked by exacerbations and remissions. For five days he had ceased to be able to move his legs, and for one day he had noticed that his legs were blue. There had been a slight cough with a little expectoration since the illness began, and some shortness of breath for five days. Neither the past personal history nor the family history presented anything noteworthy. He had not been abroad; there was no history of rheumatism or syphilis.

On admission the patient was poorly nourished and markedly anæmic. His mouth and fingers were twitching. The distal parts of both lower limbs were purple in colour, cold, painful, and tender. Demarcation lines divided the purple from the normal skin four inches above the knee-joint on the right side, and two inches below the knee-joint on the left. Immediately above the demarcation lines the limbs were hot, œdematous, and acutely tender. No pulsation could be felt in the femoral or popliteal arteries. Pain and thermal sensation were absent over the affected areas, and sensation to touch was impaired. The apex beat of the heart was in the fifth left interspace four inches from the middle line. The heart's action was rapid, and some irregularity was present. The sounds lacked tone, but no murmurs were heard. The cardiac dulness was difficult to determine owing to the presence of emphysema in marked degree. Many of the heart-beats did not reach the wrist, and the pulse was irregular in force and rhythm. The arteries were thick and tortuous, and the blood pressure was equal to the weight of 130 mm. of mercury. The percussion note of the chest was hyperresonant, and the lungs obliterated the superficial cardiac dulness. The expansion of the chest and the respiratory murmur were poor. The abdomen was normal. The urine was acid, with a specific gravity of 1020. There was no sugar or blood, but a cloud of albumin appeared on boiling. The nervous system presented no abnormality except in the gangrenous areas. The temperature was 100° F., the pulse-rate was 130 per minute, and the respirations 36.

On Feb. 7th blebs appeared on the legs, and there was a papule of pus near the line of demarcation on the right side. The albumin had disappeared from the urine. On the 10th the blebs were more numerous. Pink patches had appeared on the legs, which contrasted with the purple colour of the rest of the gangrenous areas, at the upper limits of which numerous petechiæ had become visible. Some extension of the gangrene was also noticed. The general condition had deteriorated and the pulse had become very irregular, though the pain was less acute. On the 14th there was a rigor. By this time many of the blebs had broken down, and their surfaces had become raw and offensive. Some blood was removed from a vein for a blood culture and the Wassermann test was made, both investigations giving a negative result. After this there was a rigor each day, and the patient went downhill rapidly. The heart became more and more feeble, and death took place on the 17th. It proved necessary throughout to give morphia every few hours to alleviate the pain. The temperature was irregular, varying as a rule between 100° and 104°, and occasionally dropping to the normal line.

The post-mortem examination was made by Mr. E. H. Shaw on Feb. 18th. The following points are extracted from his report. The left foot and leg up to the knee were black and moist, the toes being dry. The right lower extremity up to the thigh was in a similar condition. A small hæmorrhagic infarct was found under the pleura at the right pulmonary base. The heart was enlarged. The left auricle was much dilated, and the wall was thickened. The endocardium was white. The left auricular appendix was filled by white, friable, laminated clot, which projected into the auricle. The clot was lightly adherent to the wall. The mitral valve was stenosed by adherence of both cusps at their margins to form a narrow orifice about 1¼ inches long. The segments were thick and fibrous. The chordæ tendineæ were a little thickened, as were also the aortic segments. The other valves were natural. The aorta showed some small patches of atheroma. Lightly attached to the wall of the abdominal aorta at the point of bifurcation was a partly decolourised, laminated clot with dimensions of about 1¼ inches by ½ inch. From this a cylindrical smooth red clot extended into the right common iliac artery for about two inches. There were also some small loose pieces of red clot lightly adherent to the vessel wall along the remainder of the common iliac artery, extending also into the femoral artery. The wall was deeply blood-stained and thickened. The connective tissue outside the wall was also thickened. The left common iliac artery was partly obstructed at its origin, and there were loose pieces of blood-clot extending downwards and into the femoral, the artery being deeply blood-stained. The large branches of the right iliac were plugged with clot. The vena cava was deeply blood-stained, and contained a few small, soft, red pieces of clot, and the iliac veins were in a similar condition. Near the origin of the femoral vein each vein was filled with red clot, the clot extending along and filling the femoral vein. The clot was soft and lightly adherent to the wall. The tributaries of both veins contained similar clots. The tissues of the thighs contained much lymph. From the heart blood a growth of bacillus coli communis was obtained.

For the clinical notes of the case I am indebted to Mr. E. Smeed, house physician.

Cavendish square, W.

A NEW METHOD OF TREATING CHRONIC COLI-CYSTITIS AND OTHER BACTERIAL INFECTIONS.

BY CHARLES RUSS, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

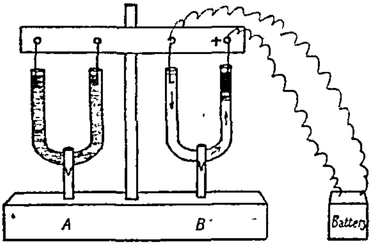
IN June, 1909, I read before the Royal Society a paper on the Electrical Reactions of Certain Bacteria and an Application in the Detection of Tubercle Bacillus in Urine by Means of an Electric Current.[1] In this paper I showed that certain bacteria suspended in an electrolyte through which a current passes aggregate at one or other of the electrodes during the passage of the current, and that the aggregation varies with the nature of the electrolyte and is probably due to affinity between the products of electrolysis and of the bacteria. I subsequently found that electrification of the bacteria in certain solutions kills them. Demonstrations were given at meetings of the Pathological Section of the Royal Society of Medicine in January, 1910; British Medical Association in July, 1910; and at the International Hygiene Exhibition, Dresden, 1911.

Since these laboratory observations I have during the last few years devoted considerable time to their application for the relief or cure of certain suppurative human diseases.

Preliminary considerations.—Since nearly all pathogenic bacteria move to the positive pole during electrolysis in sodium chloride solution (Fig. 1), I thought they might be drawn out of ulcers and infected mucous membranes, &c., if a column of sodium chloride were superimposed on the diseased area and a current passed in the appropriate direction. If the positive pole were submerged in such a column of saline and the organisms drawn to it by the current, then, as the tissues became free from the bacteria, recovery would ensue. Incidentally also the bacteria would be killed during the process.

The first cases treated (varicose ulcers, septic fingers).—In 1911 I commenced this study by applying the above-mentioned ideas to chronic varicose ulcers of the legs. These are lesions which can be seen during treatment and are accessible and easily measured. By the courtesy of Dr. C. T. Parsons I treated a short series of such cases at the Fulham Infirmary. The majority were healed. The largest was about 5 by 3 inches, and the smallest about 1 inch square. The method devised was as follows. A varicose ulcer was encircled by a special glass vessel larger than its area and fixed in a watertight manner to the surrounding healthy skin by plasticine. The vessel was nearly filled with saline solution, and furnished with a submerged anode of platinum foil. An electric current was passed from the calf resting on a wet cathode pad (bolster) through the limb, traversing the ulcer to reach the overhanging anode. In this way the bacteria in the ulcer were expected to migrate to the anode, and if they left the ulcer or were killed it would be free to heal. Many experiments as to the amount and duration of current passed were made until favourable results were usually obtained. In the intervals between treatment only a cold compress of saline was applied to the ulcer. These ulcers were of years', months', or weeks' duration, and were systematically measured as to their greatest diameters before each treatment. In the first case, to estimate the number of bacteria withdrawn by the process, a control was undertaken by planting a sample of the saline (stirred over the ulcer) before polarisation, and counting the colonies which developed from 1 c.c. and ½ c.c. on agar plates, and also after polarisation for 10 minutes. The result—namely, no growth in the second set of plates—was a sharp reminder of the importance of the bactericidal effect of the treatment, in addition to any effect of drawing organisms out of the ulcers.

FIG. 1.



Bacterial suspension, A, before passing current; B, after passing current.

In view of a friendly challenge that my electrical attentions were doing no more than rest in bed would produce, one of the patients was kept in bed and treated by ointment for 14 days. The measurements before and after this test showed enlargement of the ulcer, but it diminished as soon as I began again. Of course, the varicose factor, unless surgically removed, almost ensures a relapse, but I was satisfied after six months' attention to these ulcers that this process needed much more study.

Septic fingers.—Mr. C. R. C. Lyster last year treated several cases of acute and severe suppuration of the fingers (casualty hands) at the Middlesex Hospital by this principle of fluid electrolysis, with very satisfactory results.

Coli-cystitis.

After reading the original paper a surgeon asked me whether the bacilli might not be withdrawn from the bladder in coli-cystitis. I presently sought an opportunity to test its value in that disorder. After analysis of several thousand urines of acute and chronic cystitis one is impressed with the almost constant prevalence of colon bacilli as the invaders of the bladder. These bacilli, whether the true bacillus coli communis or one of its relations within the colon group, are small bacilli whose access to the bladder has been the subject of much speculation. Seldom, perhaps, is their route proved. It may be that their spontaneous motility supplies sufficient motive power for them to traverse the recto-vesical partition if some other abnormal factor be also present. However, the condition is well known clinically and the essential pathological features are the presence of pus and bacilli in the vesical urine in cystitis (Fig. 2) and of bacilli only in bacilluria.

---

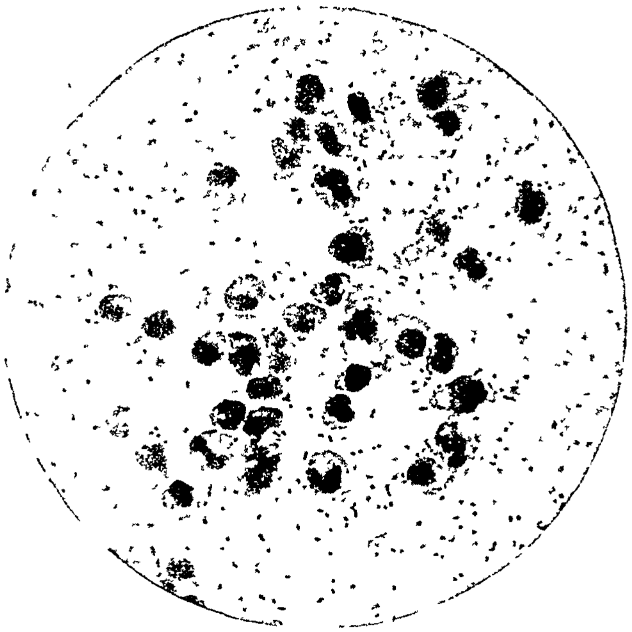
FIG. 2.



The bacilli and pus cells in the urine of a typical case of coli cystitis before electrical treatment. 1/6th objective. Gram's stain.

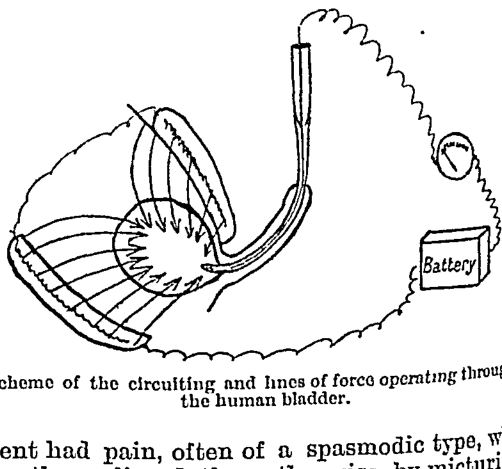
The cure of the condition involves the extermination of these organisms, and this is a problem of some magnitude. The bacilli multiply at a rapid rate in the urine and bladder mucosa, and although the majority are expelled by urinary voidance the residual bacilli soon reproduce and the cycle of events proceeds. Recovery in a chronic case is characterised by diminution and disappearance of the pus, and later the same happens to the bacilli. Coincident with these changes there is a loss of the morbid symptoms clinically. The remedies in ordinary use are intended to act in various ways. By the use of drugs of the urotropine class we endeavour to kill the bacilli by producing a germicide in the urine—a state inimical to their multiplication. Lavage cleans the bladder, but needs repetition to deal with the new bacillary population arising from the survivors of the last wash-out. Injections of germicides need to be weak enough to spare the mucosa from injury whilst killing the organisms. Vaccines acting *viâ* the blood stream appear to alter the absorption of the coli toxin and induce a better feeling in the patient; and a certain number of recoveries have followed their use. All these methods are notoriously unsatisfactory.

As a laboratory experiment I had so often seen the migration of the colon bacilli to the anode in salt solution (Fig. 1) that it seemed not unreasonable that the same movement and the lethal effect might be induced if similar conditions were arranged in the human bladder. Removal of the organisms dead or alive faster than they multiply is a line of treatment that must cure the disorder, and a practical test would show whether this could be done.

The modus operandi.—After voidance of any urine the patient reclined on a couch, and a broad abdominal belt of layers of lint was passed round the lower part of the trunk. This belt, which carried a core of metallic gauze, was wrung out with warm salt solution before application. Next a rubber catheter, furnished with several perforations round its eye, was passed into the bladder. The free end of this catheter was connected to 8 inches of glass tubing, which in turn was joined by a short length of rubber tubing to a glass funnel—everything being sterilised. A few ounces of the salt solution (2 per cent.) were next passed into the bladder, and the glass tubing, after disconnexion from the funnel, was clamped a little above the level of the pelvis. A platinum wire 6 to 8 inches long was next passed down the catheter to within 2 inches of its eye. This wire was connected to the positive and the core of the belt to the negative poles of the electric battery. The fluid in the bladder rose and fell in the glass tubing with the respiratory movements, and its movement served as an indicator that the catheter eye was within the vesical cavity. A constant current was now gradually turned on to a magnitude of 3 to 5 milliampères, and was allowed to run for 20 or 30 minutes. The scheme of the system is shown in Fig. 3. The patient feels no discomfort during the process.

Dr. A. Allport kindly provided me with my first case of chronic coli-cystitis—a patient whom, however, he also suspected of a vesical stone. The patient had pain, often of a spasmodic type, which was rather relieved than otherwise by micturition. Stone being suspected, the bladder was sounded, but under great difficulty owing to the extreme pain and vesical tenesmus which the sound produced. No stone was detected, and cystoscopy was impossible except under an anæsthetic. The patient, who was 63 years of age and weighed about 16 st., had suffered from cystitis for four years. His condition was one of one- or two-hourly frequency by day and two- to three-hourly at night. An examination of his urine showed no tubercle bacilli. He passed no more than 3 ounces of urine at a time, which contained 2 drachms of pus and was teeming with colon bacilli. It was acid in reaction, and was also examined chemically and by culture. I treated this patient on the above lines daily or on

FIG. 3.



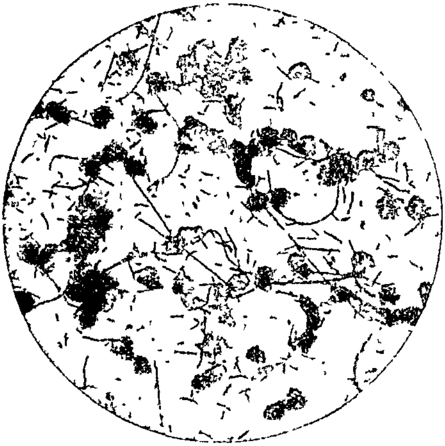
Scheme of the circuiting and lines of force operating through the human bladder.

alternate days for about three months with varying strengths of electric current, duration of treatment, and various reagents, but although his condition improved the progress was not so great as I anticipated. The treatment was suspended for three months, after which the patient was very anxious to resume the electrolysis, and I decided to try another reagent—namely, iodic acid. This substance has certain excellent electrochemical qualities, and I used it eventually in a strength of 1 in 1500, the wire now being the cathode, and with very good results. After a few weeks his pus had diminished to ⅓ drachm in 5½ ounces of urine, but his pain persisted, and while temporarily using a more rigid catheter I felt a grating sensation, suggesting a calculus. By this time his bladder was so much more tolerant that Dr. Allport had no difficulty in passing a metal sound, when a stone was detected, which was presently crushed in hospital. His urine still contained a trace of pus and numerous transformed bacilli, but with no electric treatment he has not been out of bed for urinary voidance for three months, and holds urine three hours and sometimes longer by day. He is actively carrying on his occupation.

I next treated a short series of chronic cases, chiefly men over 70 years of age, and having about an ounce of residual urine. They were worried by night and day frequency, and had had chronic cystitis for several years. After a few weeks' treatment by iodic acid electrolysis they were all improved. Their pus was reduced, and their frequency quickly improved by a minimum of 33 per cent. on their average number of voidances for the 24 hours—i.e., 12 frequencies became 8 per 24 hours. The frequencies in these cases had to be recorded carefully by day and night before and during treatment, as the patient's impressions are liable to be vague. These patients had not the additional assistance of vaccines, drugs, or other medication. The important question of relapse is one that I am unable at present to answer, but provided the bacilli have been transformed (Fig. 4) there is apparently no relapse.

An effect upon the bacilli.—I have mentioned the germicidal effect anticipated, and also that of drawing the organisms electrically from the affected part. The former was proved on more than one occasion by finding cultivations sterile, which I made from the vesical fluid (iodic acid and urine) at the end of a treatment. This lethal effect was, however, not invariably produced, and while these patients were improving as to their frequency and their pus production there still were bacilluria and some pus present. I was not satisfied that the diminution of these factors was large enough to account for the clinical improvement. However, microscopic examination of the urine showed a new and, I believe, important feature. I refer to the changed appearance of the bacilli, which is manifest in Fig. 4. This is a microphotograph of one of the urines. The average size of a colon bacillus is that of almost the smallest of the bacilli in the field. In cases of chronic cystitis which are slowly recovering from the disorder by other agencies than electricity one sometimes sees a lengthening of the bacilli in their urine, but it is only a fraction of that in Fig. 4. The attenuation of the bacilli has been brought about by the vesical polarisation which I administered. Now if this visible attenuation of form has been accompanied by a reduced bacillary virulence, we have an explanation of the benefit induced in the patient. Reduced bacterial virulence must be associated with less inflammation, which in cystitis is evidenced by less pus formation. Reduced inflammation of the bladder means more tolerance of distension—i.e., less frequency. There is also a change in the staining reaction of the bacilli to Gram's stain. Within the same bacillus there is often a Gram negative and positive effect. If this is the true interpretation of the changes in the bacilli, then the factors in the process which most rapidly produce this attenuation must be precisely determined and brought into action for the benefit of the patient. I have also produced a moderate lengthening of the true bacillus coli communis by electrolysis in U tubes in the incubator. I hope to make more extensive observations in the future of this effect, which was quite unanticipated.

FIG. 4.



Showing a drop of urine containing pus cells and the transformed colon bacilli. 1/6th objective. Gram's stain.

Gonorrhœa.—I also took the opportunity of trying the process in two cases. I failed in one of a year's duration, though the volume of discharge was reduced. In the other of three weeks' duration I arrested the discharge after the fifth dose of current. The instruments and technique were different and so was the fluid used, but I have confidence in the developments of the process in gonorrhœa.

In conclusion, I acknowledge the assistance of a grant in aid of the expense of this research by the Royal Society. I am also indebted to Mr. E. H. Fenwick, Mr. Lyster, Dr. Allport, Dr. Parsons, and Dr. Wall for their interest and assistance in providing cases.

Beaumont-street, W.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held, by the courtesy of Dr. T. Stewart Adair, at Storthes Hall Asylum, near Huddersfield, at 3 P.M. on Thursday next, Feb. 19th, under the presidency of Dr. James Chambers. The asylum will be open for inspection from 11 A.M. that day, and Dr. Adair kindly invites members to luncheon at 1.30 P.M. A paper on the Clinical Significance of Katatonic Symptoms will be read by Dr. Henry Devine, and tea will be provided after the meeting. The quarterly dinner will be held that evening at the George Hotel, Huddersfield, at 6.45 for 7 o'clock.

ERRORS OF REFRACTION IN SCHOOL CHILDREN.[1]

BY ARCHIBALD STANLEY PERCIVAL, M.A., M.B. CAMB.,
SENIOR SURGEON TO THE NEWCASTLE EYE INFIRMARY.

THIS subject has been allotted to me by the authorities, and I may say in passing that it is not the one I should have chosen myself; for obviously there are some of you who only wish to know the best and shortest way to diagnose an error of refraction, while others wish to correct that error themselves. It will, I fear, call for much forbearance from one section or the other to listen to all this paper.

Much time will be saved by proceeding in an orderly manner. Now children may be divided into two classes—those who do and those who do not know their letters; these illiterate children we will denote by the symbol Il. Insist on having a report from the school teachers of all the children who seem to have a difficulty in seeing (D), headache troubles (H), &c., and a further note if they are illiterate (Il). Make a list in a vertical column of all the children you are going to examine, with the notes of the reports you have received. (See Table.)

We will suppose that Arthur Roberts is reported to have defective sight and to be illiterate; Richard Doe also illiterate; Thomas Anderson is said to suffer from headaches, and so on with the others.

1. Examine the external appearance of each child's eyes with the large lens for focal illumination in one hand, and a spring watchmaker's glass in your eye so as to see whether any corneal trouble is present—ulcers, nebulæ, &c.—or whether there is any haziness of the pupil that may be due to lamellar cataract. Note at once on the paper opposite the child's name anything that you notice —e.g., C.C.S. for convergent concomitant strabismus, or the ordinary internal squint, D.S. for divergent squint, Neb. for nebula, &c. Now we suppose that we have found that Arthur Roberts has a nebula in each eye, while Richard Doe has a squint and also a nebula in his right eye. Then our table will begin in this way:—

Name.		Report.		Observations.
A. R.	... ...	Il.	......	R. Neb. L. Neb.
R. D.	... ...	Il.	......	C.C.S. R. Neb. L.

Now as in the first case both the corneæ are nebulous it is impossible to discover an error of refraction, so do not waste time, but send the child to his medical man for appropriate treatment for the nebula—thiosinamine or Pagenstecher's ointment or dionine, or whatever the child's doctor thinks is most fitting. This is, of course, not a case of refraction, and we must stick to our subject if we are to get through with it.

In the second case we at once put in homatropine into the clear eye—i.e., the left eye. In three-quarters of an hour or so the homatropine will have dilated the pupil and paralysed the accommodation so that the retinoscopy result can be absolutely relied upon. Suppose that by retinoscopy we infer that + 5 D. should be his correction for distance when under homatropine, we take off 0·5 D. for the homatropine, and order + 4·5 D. for each eye to be worn constantly. As before, we send the child to his medical man for treatment for his nebula. We cannot find what the correction is for his nebulous eye, and in the meantime it is best to order the same correction for it as the clear eye. When the nebula has cleared up this eye should be tested by retinoscopy under homatropine and the proper correction ordered for it. It is, however, most important in any case of converging squint to order convex glasses, if required, as early as possible, as by this means the squint is far more easily and speedily cured.

The literate children, those who can read, must not be treated in this summary way; they must be tested with test-types.

2. After noting their defects as discovered by the previous external examination, ask each child in the absence of those who have not yet been examined to read the last line of the test-types, which are placed at a distance of 6 metres or 20 feet, with each eye separately. If they can read *this* line satisfactorily with each eye note R. 6/6, L. 6/6 opposite their name, and they may be passed without further examination provided that you have heard no complaint of eyestrain or difficulty in seeing.

Perhaps I may be allowed to say a word about these visual tests. Here are a set of test-types. The theory of them is perfectly simple. The large letter at the top subtends an angle of 5′ at a distance of 60 metres—i.e., about 66 yards; the letters of the second line subtend the same angle at a distance of 36 metres. The letters of the fourth line subtend the same angle of 5′ at 18 metres, those of the sixth line at 9 metres, and those of the seventh line at 6 metres. Now standard vision may be regarded as that vision which will make it possible for a patient to recognise letters which subtend an angle of 5′.[2] If, then, Arthur Brown, say, with his right eye can read the seventh line at 6 metres, his right eye has standard vision, and we denote the result of our examination by 6/6. The numerator always means the distance at which the patient stands during the test, while the denominator always means the greatest distance at which a person of standard vision could stand, and still be able to read the specified line.

We will suppose that Thomas Anderson is unable to read the bottom line, then find out which line he can read with each eye separately. Suppose that with his right eye he can just read the sixth line, which he should have read at a distance of 9 metres, whereas he is really only 6 metres from the test-type. We note this result by the symbol 6/9—i.e., 6/9 of standard vision. Never simplify such fractions; do not, for instance, put down 2/3, the fraction 6/9 tells us directly that it is the result of an examination at 6 metres distance. Also never speak of normal vision; *standard* vision is not normal or average vision any more than 5 ft. 10 in. is a normal height, although it may be the standard height for certain occupations. Much confusion is occasioned in the law courts by speaking of 6/6 as normal vision, instead of standard vision.

But we must return to Thomas Anderson. Let us suppose that with his left eye Thomas Anderson can only read the second line; we note then L. 6/36, for at a distance of 6 metres he can only read what he ought to be able to read at a distance of 36 metres.

---

[1] Being a paper read on Jan. 23rd, 1914, at one of the scientific meetings of the British Medical Association (Newcastle-upon-Tyne Division).

[2] Some letters are much easier to discern than others. In Snellen's test-types [illegible] subtends an angle of 5′, while the [illegible] G from C, subtends an angle of 1′ [illegible] visible.

3. Now repeat the test with the pinhole diaphragm. This is *the diagnostic test* of an error of refraction, though it is never mentioned in the ordinary books. I will pass round some lenses and pinholes for you to see for yourselves what a delightfully simple test it is. Put up one of the lenses before your eye so that some if not all of these test-type letters are blurred. Then hold the pinhole in front of the lens close to your eye, and at once you will be able to see much more clearly. This increase of definition is, of course, due to the fact that the pinhole diminishes the size of the circles of confusion on your retina, so that each point of the object is represented by a tiny circle on your retina, instead of being a big circle of confusion.

Hence whenever the visual acuteness of a person is increased by looking through a pinhole, it is absolutely certain that his defective sight is due in part, if not entirely, to an error of refraction. If the defective sight is not improved, or if the vision becomes less, it is certain that there is some other defect in the eye. It may be opacities in the media, choroiditis, choroidal atrophy, or something wrong with the optic nerve or with the brain, as in amblyopia.

Suppose that we find that our Thomas Anderson with the pinhole can read the seventh line—i.e., 6/6—with his right eye, but only the top letter with his left eye. From this we at once infer that Tommie has an error of refraction that must be corrected in his right eye, and that he has some disease or amblyopia in his left eye. As indicated by the symbol H, we remember that his teacher reported that he suffered from headache; we therefore ask the boy about this symptom. We may find that it is not really a headache but a pain in one or the other eye. Quite often the pain occurs in the eye with the better vision, apparently because it is the more used and strained, as it in that case always ceases when the correction is worn. Affections of the fundus in childhood rarely cause pain. It is always well to remember that the teacher's reports are only suggestive, they never warrant a diagnosis based on them alone.

Name.	Report	Observations.
A. R.	P, H.	R. Neb. L. Neb.
R. P.	H.	C.C S. R. Neb. + 4·5 D. L. + 4.5 D.
T. A.	H. . .	R. 6/9. P. 6/6. L. 6/36, P. 6/60.
A. B.	—	R. 6/6. L. 6/18, P. 6/6.

We then put homatropine into each of Tommie's eyes and get him to wait while we examine in the same way each of the other children on our list in turn. Suppose that the next child, Arthur Brown, after this examination has the following notes put after his name: "A. B.: R. 6/6; L. 6/18, P. 6/6." Most probably he will have no difficulty in seeing, and will have made no complaints of headache or eyestrain. Is there any necessity to order him glasses? I think there is for this reason, that if we do not he will use his left eye less and less until it becomes amblyopic. From the note with the pinhole diaphragm we infer that with an optical correction his left eye will now see perfectly, and therefore it is most important that during his school life he should be provided with this correction, as amblyopia develops almost entirely in early life. Later, his employment may necessitate his dispensing with glasses, but should an accident occur injuring his good eye, he will always be able to see perfectly with his left eye when furnished with the correction.

Always do your best to avoid the onset of amblyopia by encouraging the faulty eye to do its fair share of work.

Many children will be reported to you as being unable to see the blackboard, though they see well close at hand. Beware of assuming that all such children are myopic. Some of them will be found to suffer from the so-called "spasm of accommodation." This will at once be discovered on testing them under homatropine by retinoscopy, and they will be found to require convex glasses, if any at all. In the last case, if they are emmetropic, or if their error be only about + 1 D., do not order them any glasses, but give them gutt. atrop. ¼ per cent. three times a day for three days, and allow them to stay from school for 10 days or so until the effects of the atropine are beginning to wear off.

Myopia.—In cases of genuine myopia, as found by retinoscopy, there are several points to be considered.

In slight cases, those of about − 2 D. or less, order the appropriate glasses to enable them to see the blackboard at school, but inform the parents that if there is no further increase of the myopia there will be no necessity for them to wear glasses when they grow up if their work is close—e.g., any work in the shops (such as that of a fitter) or in the mines or any office work, but that they will always require glasses for seeing at a distance. This is important for the parents to know, as myopes are *unfitted for the army, navy, or mercantile marine,* or any occupation in which distant vision without glasses is desirable.

In more advanced cases of myopia there is a great tendency for it to increase, so special instructions must be given to the parents and to their teachers. As the working distance of such patients is much too close their eyes are strongly converged and rotated downwards to see the book or work that is below them. Now, if we think of the muscles that are chiefly employed in depressing eyes that are already strongly converged we remember that they are the superior obliques. When this muscle contracts, especially if there is any synergic action of the inferior oblique, we see at once that the eyeball must be compressed laterally by these encircling muscles, which have no intracapsular ligaments to keep off injurious pressure from the eyeball. It is clear that this lateral pressure will tend to lengthen the eyeball, to make it the shape of a lemon, and hence to increase the myopia, to cause posterior staphyloma, and even retinal detachment. The necessary instructions immediately follow from this note on the pathology of myopia. The eyes must not be rotated downwards. The work should be raised nearly to the level of the eyes, the head being slightly inclined, and held as far off as convenient, at least 12 inches. Books should be placed on a suitable bookrest, or upon a high sloping desk on which all writing should be done. The illumination should come over the left shoulder so that the letters as they are written may be distinctly seen, and not fall in the shadow cast by the writing hand.

Many authorities habitually undercorrect myopia. I give the full correction under homatropine, unless the myopia is extreme, above − 15 D., as I find that the effort to see distinctly with an undercorrection strains the eyes far more than when the full correction is given. I have never found any reason to alter my practice when sufficient care is taken to avoid the action of the superior oblique muscle.

I may as well now give general directions for the treatment of other forms of ametropia.

Hypermetropia.—Should the spectacles be worn constantly or only for near work? In the absence of squint, and when the vision is 6/6 without any symptoms of headache or eyestrain when viewing objects at a distance, do not insist on the glasses being worn constantly. With an error of + 3 D. or more they should be ordered to be worn at school and for all close work. But if the error be only about + 1 D. or + 1·5 D. do not order them. What is the use of ordering + 1 D. glasses to children who have about 15 dioptres of accommodation to compensate for such slight errors? However, remember that in a case of internal squint the correction if over + 1·5 D. must be worn constantly.

Astigmatism.—The whole of the astigmatism found by retinoscopy under homatropine should be corrected by appropriate cylinders, and if there are any symptoms whatever, whether defect of sight or headache or eyestrain, they should be worn constantly. If the astigmatism be oblique the correction is almost certain to be uncomfortable at first; if the discomfort continues for more than three weeks it is well to examine the patient again. It is very common for those who have worn an astigmatic correction for some time with comfort suddenly to complain of discomfort when using them. In such a case it will be nearly always found that the frames have got bent so that the setting of the axis of the cylinder is wrong. All that is necessary is to send the glasses to the optician to have the frames readjusted.

Anisometropia.—In this condition the refraction of the two eyes is different. There are three principal varieties—two logical divisions, the second being subdivided into two varieties: (1) Those who have binocular vision. (2) Those who have not binocular vision: (*a*) Those who use their eyes alternately. One eye is then generally slightly myopic, while the other is hypermetropic; such patients use one eye for close work and the other eye for distance. (*b*) Those who only use one eye, the other being amblyopic. This is the condition that is threatened by every case of squint, and every possible effort must be made to avoid it.

(1) In this class where binocular vision is present the difference of refraction will usually be small, and the full correction should be given to each eye, even if the difference should turn out to be as much as + 4 D. A fully corrected anisometrope may complain of some discomfort at first, which is due to the different prismatic action of the two lenses, when he turns his eyes in extreme directions. When he has learnt to move his head instead of his eyes the discomfort will disappear.

(2, *a*) Theoretically, of course, the correction should be given to each eye, and stereoscopic exercises enjoined so that he may obtain binocular vision. But, practically, these stereoscopic exercises have to be continued for such a long time that no child will have patience enough to persevere with them sufficiently to obtain any valuable result.

(2, *b*) Every effort must be made to regain the sight in an amblyopic eye, and the younger the child the speedier will be the recovery of its sight. The full correction for each eye should be worn constantly; and at meal times the better eye should be covered by a piece of paper or card to force the child to eat his meals with the feeble sight of his amblyopic eye. It is important that the exercise should not be too exhausting to the eye, and that it should be regular, frequent, and not too long continued. Precisely the same course should be followed in every case of squint. The straight eye should be covered up, and the squinting one forced to do all the seeing necessary at meal times.

Retinoscopy.—I do not attempt to explain the principles of retinoscopy to those who are not familiar with the method, but to those who do practise it I should like to give one or two hints that will be found to save time enormously.

1. If the red reflex from the fundus is dull, and if it moves only slowly on rotation of the mirror, the error must be considerable. Do not waste time by trying weak lenses; indeed, it may even be difficult to see which way the reflex moves; put in a + 7 D. at once and make another observation. If the reflex is still indistinct and the movement doubtful, substitute a − 7 D. for the convex glass you have put in, and the reflex will look brighter and the movements will be more rapid and easier to see, showing that you are nearing the correction.

2. One observation is enough if proper attention be paid to it. Do not go on wagging the mirror a dozen times, it wastes time. It is just like percussing a chest a dozen times over the same spot; no further information is gained after the first percussion if the observation is made with proper attention.

Newcastle-on-Tyne.

A CASE OF "SPASTIC" CONSTIPATION.

BY RICHARD GOMPERTZ, M.B., B.S. LOND.

THE patient, a man aged 39, has been under treatment at Duff House, Banff. Before admission he complained that for the last five years he had been increasingly troubled with constipation until his bowels never acted except under the influence of an aperient. One year ago he was examined by means of the X rays, and special attention was paid to the cæcum, about which it was thought that adhesions might exist, but nothing abnormal was found. The treatment then prescribed, and most carefully followed, consisted of massage to the abdomen, aperients, and a diet made up of foodstuffs such as porridge, brown bread, green vegetables, &c., which were chosen on account of the large amount of stimulating residue which they leave. His condition, however, failed to improve under this *régime*, and he was admitted to Duff House.

On arrival the patient complained of a feeling of fulness and discomfort in the region of the cæcum and ascending colon. He stated definitely that this sensation was aggravated by taking food, and was accompanied by irritability and depression. He had no gastric indigestion, and had never been troubled with feelings of weight or dragging at the back passage and had not suffered from piles. A motion was seldom produced by an enema, the rectum being usually empty.

A series of X ray photographs was taken by me in the X ray Department at Duff House, and it was found that the bismuth passed with normal, or even greater than normal, speed through the intestine

FIG. 1.

until it reached the splenic flexure. (Fig. 1, 24 hours after meal.) It was expected that the next stage would be the collection of a large mass of fæces in the pelvic colon and rectum, and that the case would prove to be one of common constipation of the usual form. The next photograph showed, however, a more interesting state; that portion of the bismuth which had reached the transverse colon had been rapidly transferred to the pelvic gut, as was expected, but the descending colon was now contracted and remained in this condition for a considerable time. Fig. 2, which shows this condition well, is reproduced from a photograph taken 32 hours after the meal; by comparing it with Fig. 1 it will be noted that the transverse colon is also contracted. Fig. 3 shows the condition 16 hours later; the transverse colon is admitting material, but the descending colon is still closed. The last photograph reproduced (Fig. 4) was taken 54 hours after the meal, and shows nearly all the bismuth in the descending colon or lower, but even at this time the spasm has not completely disappeared. It seems that this contracture would overtax the propulsive powers of the cæcum and ascending colon, and this idea is borne out both by the patient's sensations and by the unusual size of the cæcum.

In view of these X ray findings it appeared desirable to give a concentrated diet with little residue; to avoid entirely those aperients the action of which is largely to stimulate the large intestine, substituting for them belladonna; and to limit abdominal massage strictly to manipulations directed to empty the overloaded cæcum. Treatment was therefore begun on these lines and has met with success. A pill containing one-sixth of a grain of belladonna was given three times a day for the first few days; the feelings of discomfort vanished and normal motions were passed, the patient continuing to have daily evacuations with no medication whatever.

It is hardly surprising that the former X ray examination, at which bismuth was introduced by the mouth and rectum, led to no positive findings, for such a condition as is here described could only be recognised by means of a series of photographs.

For permission to publish this case I am indebted to Dr. E. I. Spriggs, the senior physician at Duff House.

Banff.

EXTRA-ARTICULAR ANKYLOSIS OF THE INFERIOR MAXILLA

DUE TO FOREIGN BODIES IN THE SCALP FOR TEN YEARS.

By WILLIAM MACDONALD, M.B., C.M. ABERD., L.R.C.P. & S. EDIN.

THE peregrinations of foreign bodies are well known, and the case described below gives additional proof of Nature's untiring efforts to get rid of her enemies, though if unaided they may be futile. In the temporal region foreign bodies, such as a piece of wood, a sequestrum, or pus, may be equally disturbing influences, since they may travel downwards and forwards from the temporal fossa into the spheno-maxillary fissure and descend into the mouth, or downwards and backwards on to the temporo-maxillary joint. Again, a foreign body may travel downwards from the temple and become impacted behind the orbit. In this case grave mechanical interference was produced behind the orbit in front and the temporo-maxillary joint behind.

The patient, a man aged 25, consulted me on June 3rd, 1912, for a small swelling on the side of the right cheek in front of the ear above the zygoma. He gave the following history. When a schoolboy (September, 1902), engaged in erecting a goal-post, the transverse bar fell and struck him tangentially on the head at a spot near where the temporal crest crosses the coronal suture—the stephanion. He was rendered unconscious for perhaps a couple of minutes. On regaining consciousness he found a wound nearly a quarter of an inch long, and went to a cottage close by and had it bathed with cold water. On getting back to school a cold water compress was applied, and on the next day the wound was "sealed," as he termed it, with sticking plaster. The tissues in the vicinity of the wound, however, began to swell, and he had to stop work for a month, by the end of which time the swelling had extended from the side of the head on to the face so that his features were hardly recognisable on the right side. He was sent home, and there saw his medical man, who lanced the swelling and squeezed out "a quantity of semi-gelatinous red substance," which substance continued to ooze out for a few days until the wound closed and dressings were no longer required.

In September, 1903, he entered as an engineer apprentice, and in 1908 commenced his career at sea as an engineer. During these years he still had a swelling on the right temple which caused frequent locking of the jaw. This locking was so troublesome that once during his apprenticeship his medical man was called in, and he tried to overcome the locking by leverage with a cork. The locking of the jaw came on without warning and went away spontaneously. The pain was so severe that mastication and talking became very difficult. The condition would last one or two days and then pass off, but it was exceedingly inconvenient during his first voyage, as occasionally he could not eat.

In September, 1908, a surgeon was consulted and an exploratory operation was performed on the scalp over the temporal attachment by a semicircular incision between four and five inches long. An infinitesimal fragment, supposed to be steel, was found and removed. The swelling was not reduced nor did it subside. Electric massage, full strength, was tried, but as the patient suffered acute pain and mental depression this method of treatment was abandoned. Then his medical man tried counter-irritation. Iodine and blistering were used, but the condition was not improved, and the patient resumed his life at sea, plying for three years between Australia, New York, and the River Amazon.

When he came under my observation in June, 1912, there was a hard fusiform swelling occupying the right temporal region and a small fluctuating swelling over the centre of the upper margin of the zygomatic arch. Suspecting pus, I advised fomentations for three days to the fluctuating swelling, and on June 6th by a vertical incision removed a small quantity of pus, and on squeezing the sides of the wound removed seven small pieces of blackened wood like the graphite core of a cedar pencil; closely fitted together they measured 1¼ inches. The wound was packed with double cyanide gauze every two or three days, but would not close; a small sinus remained. Then there occurred marked difficulty in opening and closing the

In the diagnosis of this condition laparotomy is the only sure means of clearing up doubt, though some other evidences may be considered in a suspected case. There will be no local signs of a carcinomatous nature on abdominal palpation or on rectal or vaginal examination, no glandular or metastatic involvement, and no emaciation, but rather obesity, unless chronic stasis causes auto-intoxication or starvation. The onset will be very slow, for lipoma as a rule is one of the most tardy of neoplasms in developing, so the obstructive phenomena with periods of acute distress may be delayed and gradual. The age of development of this condition is indefinite, though it is not usual till middle life is reached.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Jan. 23rd, Dr. LEONARD GUTHRIE, the President, being in the chair. The following cases and specimens were shown:—

Dr. T. R. WHIPHAM: A case of Kala-azar in a boy aged 5 years. His father contracted kala-azar in Calcutta a year ago and died recently from that disease. In March, 1913, when in Calcutta, the boy was taken ill with fever and loss of appetite. The motions at that time were white but otherwise normal. The abdomen was enlarged when he arrived in England in June, since when he had lost weight and the size of the abdomen had increased. The child was wasted, especially in the limbs and chest; the cervical, axillary, and inguinal glands were enlarged. The abdomen measured 24½ inches in circumference; the liver extended 3 inches below the costal margin; the spleen was enormous, extending to the middle line and filling the left iliac fossa. Blood count: Red cells, 3,220,000 per c.mm.; white cells, 2200; polymorphonuclears, 46 per cent.; lymphocytes, 38 per cent.; large mononuclears, 12 per cent.; transitionals, 4 per cent; hæmoglobin, 66 per cent. The coagulation time was diminished, being 12 minutes. Leishman-Donovan bodies were present in blood obtained by puncture of the liver.

Dr. WHIPHAM also showed a case of Athethoid Movements in a girl aged 4½ years. The movements, which were present in either hand, consisted of alternate pronation and supination, which became more marked when objects were grasped. The condition was probably due to injury at the time of birth.

Dr. F. LANGMEAD showed a case of Malaria in a girl aged 3½ years. The disease, which commenced in September, 1913, was typical and accompanied by rigors. The mother had malaria while the child was being breast fed. The spleen extended downwards for four finger-breadths below the costal margin, and the liver was also slightly enlarged. Examination of the blood showed benign tertiary parasites in fair numbers, large intracorpuscular forms being seen.

Dr. ERIC PRITCHARD showed a case of Abnormal Cysts on the Shoulders in a baby 6 weeks old. The two cystic swellings were noticed immediately after birth. The presentation is said to have been that of a shoulder (left). The swellings appear to be of the nature of abnormal and persistent capita succedanea.

Dr. J. W. CARR showed a case of (?) Polio-encephalitis. The patient, a boy aged 7 years, had an attack of diarrhœa with severe headache and pains in the limbs in October, 1913. He became unable to stand or speak and also appeared to be blind. On admission in December he could not stand alone and could see only imperfectly, and there was a considerable degree of mental deficiency. The optic discs showed evidence of a subsiding neuritis. After five weeks he began to improve as regards mental condition, sight, and movement, though he still had an ataxic gait. Wassermann's reaction was negative.

Dr. F. G. CROOKSHANK showed a case of Deficiency of Endocrinic Glandular Secretion. The patient, a boy aged 32 months, did not speak and was apathetic and flaccid. Some of the features were suggestive of Mongolism. It was thought that the child had in addition to some degree of Mongolism some pituitary deficiency.

Dr. H. D. ROLLESTON and Mr. E. J. BOYD showed a case of Lymphatic Leukæmia under treatment by Benzole. A boy, aged 6½ years, developed enlargement of the cervical glands after measles and pneumonia. Subsequently the axillary, inguinal, and submaxillary glands also enlarged and the spleen was palpable. In December the leucocytes were 60,000; large lymphocytes, 54 per cent.; small, 16·5 per cent.; and polymorphonuclears, 25 per cent. He was treated with benzole, at first two minims, and later three minims, three times a day. On Jan. 13th the leucocytes were 16,000; large lymphocytes, 41·5 per cent.; small, 46 per cent.; and polymorphonuclears, 10 per cent.

Mr. PHILIP TURNER showed a case of a Dental Cyst following Fracture of an Incisor Tooth in a boy aged 12 years. The right central incisor was fractured as the result of a fall two years ago. Swelling of the jaw was noticed three months ago. There was now bulging forward of the facial aspect of the superior maxilla, depression of the palate on the right side, and widening of the alveolar process. A radiogram showed that the pulp cavity of the fractured tooth was exposed, and that the open apex led directly to the cyst.

Mr. L. E. C. NORBURY showed a girl, aged 5½ years, with Deformity of the Spine of (?) congenital origin. There was a prominence of the last dorsal and the first lumbar spinous processes. There was slight mid-dorsal lateral curvature with convexity to the left. There was no pain or rigidity. X ray examination showed a wedge-shaped condition of the first and second lumbar vertebræ. The von Pirquet reaction was slightly positive.

Dr. PRITCHARD showed a specimen of Double Hydro-Ureter (congenital) in an infant, aged 7 months, who was admitted for diarrhœa and vomiting. The bladder was not distended, but two cystic swellings could be felt internal to the anterior superior iliac spines. The obstruction appeared to have been due to valve-like pressure of the dilated ureters, the primary dilatation being probably due to congenital atresia of the ureteral orifices. The renal pelves were greatly enlarged.

Dr. J. PORTER PARKINSON showed specimens from an unusual case of Jaundice which he considered to have been acute yellow atrophy of prolonged duration. The illness commenced with a rigor. Three weeks later jaundice appeared. The liver was then enlarged but subsequently diminished until death. No leucin or tyrosin was detected in the urine.

The PRESIDENT and Dr. G. A SUTHERLAND made a communication on two cases of Transitory Diabetes Insipidus. The first case was a boy, aged 2½ years, in whom the disease lasted about six weeks. He took 12 pints of water a day, and the urine which contained no albumin or sugar was of specific gravity 1004. There was some diarrhœa and the motions were of a peculiar bluish-grey colour. In the second case, a boy aged two years, the duration was about five weeks. The main symptoms were thirst, drowsiness, and polyuria. There was diarrhœa and the motions were loose, putty-coloured, and offensive. The liver and spleen were enlarged. A possible explanation is that the intestinal derangement set up toxæmia, which acting on the kidneys prevented the output of waste products. Another explanation is that the symptoms were due to toxæmic affection of the vaso-motor centres and sympathetic system, or perhaps of the pituitary body.

SECTION OF OPHTHALMOLOGY

Exhibition of Cases —The Use of Salvarsan in Ophthalmic Practice

A MEETING of this section was held on Feb 4th under the presidency of Sir ANDERSON CRITCHETT

Dr FRANK MOXON showed cases of Congenital Diffuse Opacity of the Cornea *in two sisters* The children and the family had been healthy, there was no history of syphilis, tubercle, or miscarriages One of the children was ill with sickness and diarrhœa at a year old Both Wassermann and von Pirquet reactions were negative There was slight photophobia, but the fields of vision appeared to be normal The cornea was milky, but there was a fairly good fundus reflex The opaque spots were fairly evenly distributed throughout the thickness of the cornea Lenses and vitreous were clear —Mr J H FISHER considered that the tension in all four eyes was somewhat raised, and that there was a possibility of it being a variant of congenital glaucoma The changes were mainly in the epithelium

Mr ANGUS MACNAB showed a case of Nodular Opacity of the Cornea, which he considered bore a relation to Dr Moxon s cases In a similar one, shown before the Ophthalmological Society, the epithelium over the nodules was somewhat heaped up At the extreme periphery of the cornea there were loops of vessels which passed into the cornea and that seemed to be slightly so in Dr Moxon s cases

Mr J B LAWFORD showed a case of Brawny Scleritis The etiology as in all these cases was obscure It was an inflammatory process with much infiltration by cells, there was nothing to suggest new growth Every test applied to the case had turned out to be negative

Mr W J INMAN showed, through Mr LESLIE J PATON a case of Irido cyclitis in a boy who had been living in Africa, and was now suffering from typanosomiasis Gambiensi Last October his left eye became inflamed, and three weeks ago its fellow behaved similarly Mr Inman had the Wassermann reaction taken and it was positive, but the Wassermann reaction was positive in the disease afflicting the patient There was a beautifully marked circinate rash on the front of the thigh and enlarged soft posterior cervical glands from which failing it being found in the blood the trypanosome could generally be recovered The Rhodesian form of the disease seemed to be more severe than the Gambian Dr Daniel, whom he consulted about the case, said he would rather treat such a one with repeated small doses of atoxyl than with salvarsan —Mr E TREACHER COLLINS referred to a case of sleeping sickness which he saw with Sir Patrick Manson and described the appearances Eye diseases seemed to be very uncommon in connexion with sleeping sickness

Mr ORMOND showed a Case for Diagnosis, and Dr A L WHITEHEAD (Leeds) discussed it

Mr CUNNINGHAM showed a case of Massive Exudate in the Retina

Mr W LANG then introduced a discussion on the Use of Salvarsan in Ophthalmic Practice He reviewed the knowledge up to date, and discussed the probable mode of action of salvarsan During the early stages of syphilis, before the spirochætæ had reached the avascular tissues, salvarsan acted readily and quickly, but later it was less efficacious though gummata of iris, sclerotic and ciliary body seemed to be favourably influenced by the treatment With regard to parasyphilitic diseases the Argyll Robertson pupil had once been known to react again to light following intravenous injections of "606 Ophthalmoplegia externa and primary optic atrophy had not been definitely improved by the treatment After injecting a large dose of salvarsan into a rabbit's vein none of it was found in the cornea, though specially searched for The usual dose of salvarsan for the adult male was 0 6 gramme, and for the adult female 0 5 gramme, while if neosalvarsan were used the dose must be 50 per cent more The destruction of the parasites should be effected as soon as possible, before they had the opportunity of becoming immune to the drug He instanced cases in which greatly increased doses with that object had been efficacious Thanks largely to Mr Browning, salvarsan was now known to be a successful treatment for sympathetic ophthalmia and studies on the blood condition enabled one to foresee the onset of the condition —Lieutenant Colonel J W GIBBARD, R A M C said that although salvarsan had not supplanted mercury its action was more rapid and intense, and he narrated some striking cases illustrating this fact Secondary lesions seemed to be more intractable than primary, and relapses were more frequent The feature of secondary cases was the tendency to affections of the central nervous system, which was more often involved than was formerly supposed He did not believe this was due to salvarsan, cases were heard of more because everyone was on the look out for untoward symptoms following the use of the new drug salvarsan He knew of only two cases of cerebral nerve disturbance in 1200 cases in which the drug was used And where this did occur an increased dosage caused a disappearance of the trouble Syphilitic meningitis was more prone to relapses because of the inaccessibility of the subarachnoid space Having killed off the main army of the organisms it seemed necessary to keep in the blood a remedy which would deal with scattered survivors At his headquarters they had given 4000 intravenous injections and the soldier concerned was followed up wherever he went —Mr S H BROWNING read an interesting paper in which he detailed his cytological studies and the reasoning which led him to suggest giving salvarsan for sympathetic ophthalmitis He had had excellent results in syphilis from salvarsan given per rectum, that the drug was absorbed when so given was proved by the occurrence of an arsenical rash following the method Out of 500 to 600 cases he had not heard of a single instance of ocular palsy, optic neuritis or other similar trouble The most successful results from the method were in syphilitic iritis, gummata of the sclera also vanished in a marvellous manner under salvarsan and potassium iodide He agreed with the general opinion that in interstitial keratitis it was not much good, though there had been one or two notable exceptions His usual method was to give the drug intravenously Neosalvarsan was more toxic than salvarsan

The debate will be continued at a special meeting of the section

SECTION OF PSYCHIATRY

The Influence of Toxins on the Central Nervous System —The Importance of Disturbance of Personality in Mental Disorders —Exhibition of Specimens

A MEETING of this section was held on Jan 27th Sir GEORGE SAVAGE, the President being in the chair

Dr DAVID ORR and Dr R G ROWS communicated a paper entitled Further Observations on the Influence of Toxins on the Central Nervous System ' Experiment showed they said that toxins travelled upwards readily in the perineural lymphatics, and the irritation was continued in the central nervous system if the toxins succeeded in gaining that level Continuity of extension was an important *feature, and was as constant in the central* as in the peripheral nervous system The lymphogenous infiltration was characterised firstly, by reaction of cells of the fixed connective tissues, secondly, by proliferation of the cells of the adventitial sheath of veins and capillaries, [illegible] the cord [illegible] ly, nerve [illegible] cells was [illegible] sane and some other conditions They had found that the lymph path of the nerves was an important mechanism in brain and cord infection and probably general paralysis and tabes were lymphogenous infections Another mode of infection of the central nervous system was by the blood stream and over and above the deleterious influence on nerve tissue of organisms and toxins one had to remember the effects of products of altered metabolism, and the influence of hyper and hypo secretion of the ductless glands In the present series of experiments the authors had commenced a study of the effects of bacterial intoxication on the spinal cord, and had chosen the abdominal cavity as the site of the experiments The reasons for this were multiple (1) this site was most suitable for experiment in which one wished to exclude infection of the lymph system of the spinal nerves, (2) in order to reproduce, as closely as possible gastro intestinal intoxication and observe the effects on the spinal cord, and (3) to ascertain how far such toxic infection affected the occupied allowed the meal to settle in the stomach and separate itself from the gases always present. He then placed an opaque disc over the umbilicus and made his first screen examination and then exposed a plate. All examinations were made with the patient in the upright position. That there might be no risk of the bowels moving during the period under which they were under examination he advised that they be thoroughly emptied the day before the first examination was made, and in order to interfere as little as possible with the patient's routine the patient was first examined at 9 A.M. without having had breakfast. The second examination was made at 1 P.M., the patient having received strict injunctions to take no food in the interval. After the second examination the patient was allowed to take lunch and tea and dinner as usual. No purgative was given during the time the examination was being undergone. Taking Hertz's time-tables as his guide, he found that making examination at intervals of 3½, 8, 12, and 24 hours after the first, gave all the information obtainable in most cases, though occasionally one had to go on for 36 and 48 hours or even longer. Very often the 12 hours' examination could be omitted; this depended on the rate of progress observed on the screen. The skiagrams showed that they could demonstrate the exact position of the various organs comprising the alimentary system in health and also their variation in disease. Further accurate information regarding their conformation under the two conditions could be revealed. They could also learn something about the rate of progress through the alimentary canal of its contents, and should delay be one of the conditions present attention would be directed to the affected area with unerring truth. Lastly, it could give invaluable information with regard to the condition of the walls of the various organs, whether they were healthy or in a state of degeneration and atony. In those cases in which an operation was called for, the surgeon had at his command a method of investigation which enabled him to decide before opening the abdomen the nature of the operation he would probably be called upon to undertake and the extent of diseased intestine he had to deal with. Radiograms were shown of a case which demonstrated clear evidence of degeneration in the cæcum, ascending colon, hepatic flexure, and right half of the transverse colon, and in which Mr. Stiles, instead of doing a complete Lane's operation, resected the portion of large intestine mentioned and planted the ileum into the healthy left half of the transverse colon with very happy results. Another radiogram showed an even more advanced stage of atony, involving as it did the whole of the colon. Prints of this case were shown to Sir Arbuthnot Lane, and on the strength of them and of other clinical evidence he advised that a colectomy should be performed. Another case was that of a woman, aged 41 years, with symptoms attributed to intestinal stasis, headache, malaise, constipation, and unfitness for work. The radiogram showed that she had a very low colon and there was marked delay in the cæcum and colon. Mr. Stiles performed an ileopelvicolostomy, and eight months afterwards she was perfectly well. A radiogram taken then after a bismuth meal showed that a great part of the food had regurgitated into the transverse colon. Yet all symptoms which were supposed to be due to absorption from the large intestine had disappeared. This case seemed to bear out Professor Adami's contention that absorption from the large intestine did not take place, at any rate to the extent it was supposed to by some physicians.—Dr. G. Lovell Gulland thought that there might be spasm of the bowel and that the appearance which this presented in the radiogram might occasionally mislead one.—Mr. Harold J. Stiles said that the more he saw of radiography the more highly did he think about it. It was most useful in cases of disease of the large intestine, though one could make a very correct diagnosis without radiography. Mistakes in radiograms might be due to faulty interpretation. He referred to Jackson's veil and its effects.—Professor William Russell, Dr. T. M. Burn-Murdoch, Mr. A. Scott Skirving, and the Vice-President also took part in the discussion.

Dr. Byrom Bramwell gave a communication on Diffuse Sclerodermia: its frequency, its occurrence in stonemasons, its treatment by fibrolysin, and elevations of temperature due to fibrolysin injections. He said that diffuse sclerodermia was a very rare condition. Dr. Phineas S. Abraham, the writer of the article on Sclerodermia in Allbutt and Rolleston's "System of Medicine," stated that McCall Anderson met with 2 cases in 11,000 diseases of the skin, and Crocker 2 in 10,000 cases. In 17,140 general medical cases seen in his (Dr. Bramwell's) hospital practice (8502 in-patients and 8638 out-patients) there were 7 cases of diffuse sclerodermia, and in 10,000 general medical cases seen in private practice of which he had kept notes there were 2 cases. Cases of diffuse sclerodermia came at least as frequently under the care of the general physician as under the care of the dermatologist. In 21,000 cases of diseases of the skin seen by McCall Anderson and Crocker, there were 4 cases of diffuse sclerodermia, while in his 27,000 cases of general medical disease there were 9 cases of this disease. His next point was the relatively frequent occurrence of diffuse sclerodermia in stonemasons. In his 9 cases 5 were stonemasons and one was a coppersmith, who also was accustomed to work with a cold chisel. The only apparent cause which he was able to suggest for the relatively frequent occurrence of diffuse sclerodermia in stonemasons was the holding of a chisel in the hand during cold weather. In all these 6 cases the disease commenced in the hands. In none of these was there any history of syphilis. Dr. Phineas Abraham made no mention of the occurrence of this disease in stonemasons and he informed him (Dr. Bramwell) that he knew of no writer who did so. He felt certain that his own experience on this point could not be peculiar. He had been so impressed with the occurrence of sclerodermia in stonemasons that in the last three cases which had come under his observation he had correctly suggested the occupation of the patient as soon as he had seen and felt the hands and before he had asked him a single question. The next point to which he referred was the marked improvement which resulted in some of his cases of diffuse sclerodermia from subcutaneous injections of fibrolysin. In two of his cases the injections, which at first produced no disturbance of temperature and pulse, later produced marked elevations of temperature. In both cases these temperature alterations were identical in character. In a case of disseminated sclerosis a very high temperature (105·8° F.) followed an injection of fibrolysin. Dr. Bramwell then drew attention to the close resemblance in some of its clinical features of diffuse sclerodermia to Raynaud's disease. In almost all of the cases exposure to cold produced the same cold, blue, dead condition of the hands which was such a striking feature of Raynaud's disease. In four of the cases painless sores, which were very slow to heal, developed on the knuckles or finger tips, apparently as the result of slight injuries; in one case the tip of one of the fingers became gangrenous. In one case shown to the society the condition when he first saw it 14½ years ago was typically that of sclerodermia—the hands, feet, face, and thorax were affected. The hard, brawny, swollen condition of the hands and the hide-bound condition of the face and front of the chest had now in great part disappeared. The fingers had become bent in towards the palm and the tips of several of them were destroyed or distorted as the result of trophic lesions, highly suggestive of Raynaud's disease. Further, nævi and pigmented patches characteristic of xerodermia pigmentosum had developed on the face, chest, and back. Hæmatinuria was carefully inquired for, but was not observed in any of the cases, though in several, pains, apparently rheumatic, and stiffness of the joints were complained of. The clinical features of diffuse sclerodermia were, to his mind, very suggestive of a trophic or vaso-motor neurosis, but in none of the cases were any definite objective symptoms suggestive of syringomyelia or other definite nervous lesion detected.—Dr. R. Cranston Low thought that Dr. Bramwell's experience was unusual, as most of the cases occurred in females. He thought that the rise of temperature seen after the first few injections had been given were due to sensitisation or anaphylaxis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

President's Address.—Admissions to Westmorland Lock Hospital, Dublin, since 1860.

A meeting of this section was held on Jan. 16th, Dr. T. Percy C. Kirkpatrick, the President, being in the chair. The President delivered an address dealing with the origin of some of the existing Dublin hospitals, which was illustrated by lantern slides.

Dr. G. E. PUGIN MELDON read a paper on Admissions to the Westmorland Lock Hospital, Dublin, since the year 1860. He illustrated his remarks by charts, showing the yearly admissions and also the diseases. The decline in the number of admissions he attributed chiefly to three causes—namely, less acute symptoms, closing of irregular houses in the city, and change in the type of prostitute. He also showed tables of the birthplaces of the patients.

Mr. H. MOORE urged the necessity for this section of the Academy laying its views before the Royal Commission at present sitting to inquire into the subject of venereal disease. He referred to the fact that the terms of reference excluded the consideration of the conditions under the Contagious Diseases Act. He maintained that the principal source of venereal disease was the prostitutes, and that unless something was done to stop the disease amongst them and make them come up for treatment energy would only be wasted. In his opinion every medical body ought to express their opinion very definitely on the subject—i.e., unless the source of the disease is tackled it cannot be stopped. General hospitals should be called upon to undertake the treatment of syphilis and gonorrhœa, as otherwise students could not be expected to be acquainted with the diagnosis and treatment of such affections.

Dr. J. A. MATSON said he thought that the incidence of the disease was decreasing. He was struck by the objections which some respectable women who had contracted the disease had to go for treatment to the Lock Hospital. His view was that this hospital should be looked upon as the proper place for treatment of every woman so suffering. His experience was that those patients who had been treated at the Lock Hospital always sought treatment afterwards when there were manifestations of a recurrence of symptoms, but that they went to other hospital dispensaries rather than to the Lock Hospital, knowing that they would receive treatment as out-patients. He pointed out that in Dublin there was a large number of women known as "privateers" who spread infection much more than the regular prostitute. He mentioned that the increase of venereal disease in Liverpool was found to be enormous after the repeal of the Contagious Diseases Act.

Dr. R. J. ROWLETTE said that accurate statistics on the subject were most necessary, and if notification could give accurate statistics he thought the profession should declare in favour of notification, but it seemed to him that as a preventive of the disease notification would be the worst step that could be taken, as it would, he considered, put a barrier in the way of early treatment. If a patient suffering from venereal disease had to be notified, he thought the result would be that he would not seek treatment until forced to do so. He considered notification a most dangerous step, and expressed the hope that the profession would be opposed to it. He suggested that if each medical man was asked to make a return of cases treated by him without giving any names some help might be given, although he was alive to the fact that in this way there might be overlapping by the same patient consulting different doctors.

The PRESIDENT said that any return to the Contagious Diseases Act was not only unlikely and would be unsatisfactory, but was absolutely impossible and outside practical politics at present. He did not think that the notification of infectious diseases had proved the great panacea which the public health authorities would have us believe. He agreed with Dr. Rowlette that any form of notification of venereal disease would tend rather to increase the disease than diminish it. He looked forward to early and accurate diagnosis to diminish the disease. He considered that every medical man should have at his disposal the latest scientific methods for making accurate diagnosis, and this he believed would do more to stamp out the disease than anything else. His experience was that men were not adverse to treatment, but that there was some difficulty in getting them to continue it sufficiently long, but provided an early and accurate diagnosis could be made he thought that much could be done to stamp it out at all events in men. He did not consider there was any great change in the severity of the disease.

Dr. J. M. DAY, Dr. G. E. NESBITT, Dr. W. M. CROFTON, and Dr. W. A. WINTER also spoke, and Dr. MELDON replied.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Feb. 6th, Dr. David Ross, the President, being in the chair.—Dr. T. B. Hyslop read a paper to open a discussion on Neurasthenia. After discussing the question as to the prevailing confusion with regard to the term neurasthenia and to its unwarrantable extension so as to include widely different conditions which in reality pertained to other affections Dr. Hyslop discussed the mechanism of the nerve unit, the intracranial circulation, and the various processes of waste and repair, both in the normal and in the morbid. From the clinical standpoint he considered that there was no affection, or group of symptoms, or syndrome more prevalent, or more likely to become more increasingly prevalent, than that of neurasthenia. It is a disease of civilisation and also, in his opinion, a warning that over-pressure, when combined with defective bodily health, could have but one result—viz., degeneration. The nervous system in itself is capable of vast and continued exertion so long as it is adequately and efficiently maintained by the body mechanism of waste and repair, and the finer and the more sensitive the nerve mechanism the greater the need for the careful regulation of its nutritive and excretory processes. This is exemplified in connexion with some forms of nervous and mental disorder which, although frequently regarded as hereditary and therefore incurable, are in reality mainly hereditary defects of the bodily mechanism by means of which the waste and repair of the nervous system are duly effected. The truth of this statement, he thought, was exemplified in families which were prone to suffer from glandular anomalies with imperfect balance of the nutritional and metabolic processes. The part played by the internal secretions was next discussed, and examples of the results of defects in the functions of the thyroid, parathyroid, pituitary, adrenal, and testicular organs were discussed. Although we were as yet unable to form clear conceptions as to the relative rôles of the internal secretions, their importance in maintaining health was clearly evident. Undoubtedly many of the psychoses, both alternating, progressive, and permanent, might be traced to defects in these or other glands—the nervous system itself being merely a participant in the general metabolic defect. He was inclined to believe that all the rhythmical, alternating, or intermittent psychoses were due to faults in the mechanism of waste and repair as determined by the various organs of excretion and secretion. He regarded therefore every form of psychosis which is rhythmical or alternating in its occurrence as being somatic and extracranial in origin. The various effects of variations in intracranial arterial and venous blood pressure were next discussed and clinical examples given.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 29th, Mr. Chichele Nourse being in the chair.—Dr Percy Jakins showed (1) a case of Cancer of the Larynx in a man aged 43, with ulceration of both vocal cords; and (2) a case of Tertiary Syphilis of the Larynx, with paralysis of the right vocal cord, œdema of the arytenoids, and a positive Wassermann reaction.—The cases were discussed by Mr. Nourse, Mr. C. J. Heath, Mr. G. Jackson (Plymouth), and Dr. J. Coubro Potter.—Dr. Byrne replied to the discussion in the absence of Dr. Jakins.—Mr. Heath read notes of three interesting and instructive cases of Aural Suppuration.—In the discussion on the first case Dr. Potter expressed the opinion that it was not always advisable in cases of chronic aural suppuration to conserve the drum and ossicles owing to the liability of fibrous tissue to form in the tympanum after operation and thus impair the hearing. In regard to closing the Eustachian tube, this, he thought, was not always a good practice, as after operation hearing was sometimes much improved upon inflation with the Eustachian catheter.—Mr. Cyril Horsford also discussed the question of the correct treatment of the Eustachian tube. He could not agree with the view that it was a *sine quâ non* that the Eustachian tube should be closed. Was it not better to have an ear moist but hearing rather than dry but deaf? Moisture after operation might be looked on as a sign of success and not failure.—Mr. Nourse raised the question of the best treatment of the tympanic orifice of the Eustachian tube. It seemed to be an accepted fundamental principle in all cases to curette this orifice. He doubted very much if it was always correct. It would certainly have the effect of drying the tympanic cavity and might seriously impair the hearing.—In reply, Mr. Heath said that in radical operations he retained the mucosa of the inner tympanic wall and left the Eustachian tube open, because the mucous membrane required a drain, and none was so effective as the tube. To the assertion so often made that with a patent Eustachian tube the tympanic mucosa was liable to infection through it, he would reply that this mucous surface was far more freely exposed to bacterial infection through the large meatus than through the small Eustachian tube, yet it was the latter only which attracted attention. When possible he preserved the drum-head in order to prevent evaporation from the middle ear.—After Mr. Heath's other two cases had been described and discussed, Mr. Nourse exhibited a case of Double Abductor Paralysis of very short duration, and in which the clinical signs and symptoms pointed to the presence of a mediastinal growth.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A pathological meeting of this society was held on Feb. 6th at the West London Hospital, Dr. F. S. Palmer, the President, being in the chair.—The following specimens were shown. Mr. W. McAdam Eccles: (1) Diverticulitis of Colon (iliac); (2) Empyema of Gall-bladder; (3) Two-inch French Nail swallowed by infant and passed naturally; (4) Myxofibroma of Ileum causing intussusception.—Mr. Aslett Baldwin: (1) Hydro-nephrosis; (2) Carcinoma of Rectum; (3) Uterus with Sloughing Fibroid; (4) Microscopic section of Carcinoma of Breast; (5) Microscopic Section of Sarcoma of Rib.—Mr. Donald Armour: (1) Two Spinal Cord Tumours; (2) two Brain Tumours; (3) Gall-bladder and part of Liver removed for Carcinoma; (4) Carcinoma of Cæcum.—Dr. Arthur Saunders: Microscope slides from case of Lymphatic Leukæmia.—Mr. H. S. Souttar: (1) Diverticulitis of Ascending Colon with Large Stercolith: (2) Calcified Fibroma of Ovary, 4½ lb. (obstructed labour); (3) Strangulated Appendix from Femoral Hernia; (4) Gastric Ulcer perforating Abdominal Wall; (5) Carcinoma of Rectum; (6) Fibroids.—Dr. E. F. Travers: Carcinoma of Body of Uterus and Microscopic Section of Endometrium.—Dr. J. M. Bernstein: (1) Typhoid Ulceration of Cæcum, Colon, and Appendix; (2) Acute Osteomyelitis of Humerus; (3) Nasal Septum of Horse showing Glanders.—Mr. N. Bishop Harman: (1) Glioma of Eye; (2) Sarcoma of Choroid.—Dr. H. J. F. Simson (1) Carcinoma of Body of Uterus; (2) Fibroids; (3) Fibrosis of Uterus; (4) Sloughing Fibroid; (5) Extra-uterine Gestation.—Dr. R. R. Elworthy showed an extremely fine collection of interesting specimens recently added to the museum; also a large number of microscopic sections of specimens and films of organisms, &c.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 14th, Dr. P. Watson-Williams being in the chair.—Dr. Carey F. Coombs read a paper on Conditions Simulating Thoracic Aneurysm, in which he stated that three groups of cases may be recognised—namely, (1) diffuse aortic dilatation; (2) aortitis, syphilitic and otherwise; and (3) mitral stenosis producing enlargement of the left auricle with pressure signs, or hypertrophy of the conus arteriosus dexter with abnormal pulsation.—Dr. Watson-Williams showed two patients on whom an intranasal frontal sinus operation had been performed by opening up the fronto-ethmoidal cells from a point corresponding to the anterior attachment of the middle turbinal.—Dr. G. Munro Smith read notes on two cases, females aged 61 and 76 years respectively, both of whom presented during life signs simulating Malignant Disease of the Liver—namely, jaundice with enlargement of the liver and a visible and palpable tumour apparently in the liver. The diagnosis was confirmed in each case by several medical men, but after death the tumours had disappeared, and in the first case a post-mortem examination showed the liver to be normal in size and no tumour to be present. No post-mortem examination was performed in the second case.—Professor James Swain suggested that the condition was one of phantom tumour of the rectus abdominis.—Dr. J. Michell Clarke thought that the hepatic enlargement was due to engorgement secondary to cardiac failure.—Mr. J. P. I. Harty showed a case of Acute Mastoiditis involving the outlying cells alone, a subperiosteal abscess forming over the mastoid without involvement of the middle ear or mastoid antrum.

Reviews and Notices of Books.

A Manual of Venereal Diseases.

Introduction by Sir ALFRED KEOGH, K.C.B., late Director-General of the Army Medical Service; History, Statistics, and Invaliding, by Brevet Colonel C. H. MELVILLE, R.A.M.C., late Professor of Hygiene, Royal Army Medical College; Clinical Pathology and Bacteriology, by Brevet Colonel Sir WILLIAM LEISHMAN, K.H.P., F.R.S., R.A.M.C., Professor of Pathology, Royal Army Medical College; Clinical Course and Treatment, by Major C. E. POLLOCK, R.A.M.C. Second edition, revised and largely re-written, with new matter by Major L. W. HARRISON, R.A.M.C., Clinical Pathologist, Military Hospital, Rochester-row. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 318. Price 10*s.* 6*d.* net.

THE opportunity afforded by the demand for a second edition of this book has been taken thoroughly to revise and in fact to re-write it, for it was essential to incorporate the great and rapid advances of our knowledge of syphilis. The work has been well done and reflects great credit on its authors. The importance of a good knowledge of venereal disease cannot be overrated, and the writers of this book are well qualified for their task by the positions which they occupy.

Unfortunately the British Army suffers greatly from all forms of venereal disease, but there is good evidence of much improvement in this respect. The numbers of those sick in the army both for syphilis and for gonorrhœa tended steadily to increase until about the year 1886, when syphilis accounted for a daily inefficiency of 13 per 1000 and gonorrhœa of 7 per 1000. From this time the figures have fallen, and in 1910 each was responsible for less than 4 per 1000. While many causes have coöperated, Sir Alfred Keogh expresses the opinion that the chief cause of this diminution has been an increase in temperance. The chapter on the methods of prevention is one of the most interesting in the book, and it is probably the most important. The value of inculcating continence is also insisted on, and it is mainly to these two factors—temperance and continence—that we must look for an improvement in the extent of these diseases, not only in the army, but also in the general population.

A very good account is given of the spirochæta pallida and the various methods of demonstrating its presence, and a most valuable chapter is that devoted to the Wassermann reaction, which is of such great importance both in diagnosis and in treatment. We are glad to see it pointed out that there is no stage of syphilis in which the percentage of positive reactions to the test is 100, so that a negative reaction can never certainly exclude the disease, though it is too often accepted that a negative test is certain. The luetin reaction is spoken of with much favour, and we think it is a pity that this test is not employed more widely in this country. The clinical course of the disease is well described, and some good coloured illustrations of skin manifestations are given.

Perhaps the most important chapter is that dealing with treatment. The mixed treatment of salvarsan and mercury is recommended, and this agrees with the opinions of most of those who have had much experience in this matter. On the whole, preference seems to be given to salvarsan as compared with neosalvarsan, mainly on account of the instability of the latter drug; and it is stated that it would be inadvisable to employ neosalvarsan in tropical climates.

Altogether, we have been very pleased with this work. Practitioners may safely trust to its teaching and will find adequate accounts in it of all venereal conditions.

A Dictionary of Applied Chemistry.

By Sir Edward Thorpe, C.B., LL.D., F.R.S., assisted by Eminent Contributors. Revised and enlarged edition. In five volumes. Vol. V.. With illustrations. London: Longmans, Green, and Co. 1913. Pp. 830. Price 45*s.* net.

The final volume of this great dictionary contains several articles of interest to medical readers. Prominent amongst these may be mentioned "Synthetic Drugs, or Medicinal Products," by Dr. Virgil Coblenz, of New York; "Vegeto-alkaloids," by Professor Wyndham R. Dunstan and Dr. T. A. Henry; "Urine," by Dr. W. D. Halliburton; and "Toxins and Antitoxins," by Professor R. T. Hewlett. Opinions will differ as to whether the subjects of the last two articles mentioned properly fall into the category of "applied chemistry," but the difficulty of deciding what subjects to include and what to exclude will be understood. The ever-increasing applications of chemistry which lead every year to the creation of fresh industries makes the inclusion of physiological processes very generous. But it is obvious also that there are many substances which, though not of direct industrial importance, call for a reference in a dictionary that, according to the preface to the first volume, claims to give "a presentation of contemporary knowledge, both as regards the science and its applications"—and lives up to its claim. The article on urine is a purely chemico-physiological monograph, and does not refer to the use of that excretion in certain, though it may be classic, technical processes.

The list of contributors again shows the selection of admitted authorities upon the individual subjects treated. Professor Percy Frankland, for example, has written an admirable article upon water, in which he deals not only with general questions of natural supply but also with specific considerations relating to purity, action on metals, and methods of chemical and bacteriological analysis. This monograph occupies over 50 pages of the dictionary, and the importance of the subject demands adequate treatment. It is here approached from many points of view and always in the light of modern knowledge, and it has been a real pleasure to read it. The section on vegeto-alkaloids shows also exhaustive treatment, something like 53 pages being devoted to these bodies, interesting alike from a chemical and a pharmacological point of view.

In the contribution on synthetic drugs or medicinal products a useful classification is adopted into: (1) antipyretics, antirheumatics, and antineuralgics; (2) antiseptics and disinfectants, nonphenolic and phenolic; (3) diathetics; (4) anæsthetics; (5) organic arsenicals and chemo-therapeutics; (6) synthetic cathartics; and (7) organotherapeutic agents. Altogether, and considering the space at the writer's disposal, this is a very able collation of facts. The longest article of all is that on sodium by Dr. Arthur Carey, of the United Alkali Company. Chemists will appreciate the completeness with which all the processes that appertain to the great soda industry and soda products generally have been described. Mr. James Connah, of the Government Laboratory, has contributed three excellent and up-to-date articles upon tea, whisky, and wine respectively. Another Government chemist, Mr. D. A. Gracey, has written an illuminating monograph on tobacco, although we should like to have had some further particulars on the addition of sweetening agents, oils, and flavouring materials to tobacco, for this is now a common practice in spite of the Pure Tobacco Act of 1842. There is very little pipe tobacco sold now which is free from foreign flavourings that bear no sort of likeness to the flavour of the real pure leaf itself.

Another exhaustive article is that on sugar, contributed by a well-known authority, Mr. B. E. R. Newlands, who unfortunately died recently. The distinguished expert, Dr. Julius Lewkowitsch, who contributed the articles on tallow and certain oils, also died a short while ago; while Mr. John Heron, a classic authority on the starches, and the writer of the articles in the dictionary on this subject, is now unfortunately amongst the contributors described in parentheses as "the late."

At the outset we congratulated Sir Edward Thorpe on his choice of contributors. We beg to congratulate him again, now that we have completed our review of the series, on having received the coöperation of men obviously eminent in the subjects allotted to them to write upon. The five volumes present a remarkable wealth of material in regard to applied chemical science, and no scientific reference library will be without them. Now that this dictionary of applied chemistry is completed it is to be hoped that its companion on pure chemistry—viz., "Watts' Dictionary of Chemistry"—will similarly be brought up to date. The last edition of this work was issued in 1890, and the justification for the new edition of "Applied Chemistry," that chemistry has advanced by leaps and bounds since that date, applies equally to the work on pure chemistry.

The Practice of Obstetrics.

By J. Clifton Edgar, Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College, &c. Fourth edition, revised. Twenty-second thousand. Illustrated. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 1062. Price 30*s.* net.

Professor Edgar's excellent work has now reached its fourth edition and its twenty-second thousand. It contains the results of a large clinical experience and is a mine of information. The fourth edition has been thoroughly revised and much new material has been added.

A series of observations on the blood pressure carried out on 145 women in the last months of pregnancy show that the blood pressure in pregnancy is apt to be low, rarely exceeding 120 mm. of mercury. In the latter months the average is 115–120 mm., until the beginning of labour, when there is a rise of 15–20 mm. The author accepts Gerhardt's view that the displacement of the heart's apex by the growth of the fœtus has been misinterpreted as a sign of hypertrophy. In the treatment of cases of sepsis, Professor Edgar has had good results from the employment of a polyvalent serum used locally and subcutaneously in 50–60 c.c. doses every 48 hours for three doses if necessary. He has tried vaccines persistently and without success. The author's conclusions as to extraperitoneal Cæsarean section are as follows: in uninfected cases the operation does not give such good results for mother and child as ordinary Cæsarean section. Even in infected cases it has yet to be shown that the extraperitoneal operation is superior to the classical operation combined with eventration of the uterus and its subsequent removal. It must be remembered, however, that in the extraperitoneal Cæsarean section the uterus is saved for future child-bearing. Unlike most obstetricians at the present time, the author does not recognise that pubiotomy has any advantages over the older operation of symphysiotomy, and regards the danger of injuries to the maternal soft parts as about equal in the two operations.

A new section is added on Momburg's method of constriction of the abdomen for the control of uterine hæmorrhage; stress is laid upon the several dangers which may attend this procedure. They are necrosis of the intestine from the pressure, embolus from thrombus formation in the constricted aorta, failure of the heart and circulation both during the application and after the removal of the rubber band, and miscellaneous injuries from pressure. The method is undoubtedly a valuable one, but must be used only in desperate cases, and then with discretion and care. Additional space also is devoted to a consideration of cases of funnel pelvis, a contracted outlet being regarded as one in which the transverse diameter between the tuberosities of the ischium measures 3¼ inches or under. In measuring the posterior sagittal diameter Professor Edgar employs what he terms the direct manual method. In this the ulnar border of the right fist is adjusted to the sacrococcygeal joint and the upper surface of the flexed index finger or of the thumb is made to correspond to the interischial diameter. The diameter of the fist between these two points is then measured with a pelvimeter.

The book is very profusely illustrated; six of the old illustrations have been re-drawn and 51 new ones added to the text. The index is good and full, and this edition certainly should have as favourable a reception from the profession as the preceding ones.

Arterio-sclerosis: Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis, and Treatment, with a Special Chapter on Blood Pressure.

By LOUIS M. WARFIELD, A.B., M.D., Assistant Superintendent and Resident Physician to Milwaukee County Hospital, &c. With an Introduction by W. S. THAYER, M.D. Illustrated. London: Henry Kimpton. Pp. 220. Price 10*s.* 6*d.* net.

THIS useful monograph upon the important subject of arterio-sclerosis has reached the second edition and been brought thoroughly up to date. Arterial disease and degeneration are so common that they have recently received careful study from the various standpoints of the clinician, the histologist, and the experimental pathologist. The results obtained are admirably summarised and critically discussed in the book before us. Professor Thayer, in a brief introduction, strongly condemns the widespread and indiscriminate popular use of the term arterio-sclerosis as a complete and satisfactory clinical diagnosis, where tortuous temporal vessels or palpable radials co-exist with obscure symptoms.

In the first two chapters Dr. Warfield deals with the anatomy and pathology of arterio-sclerosis and gives a clear account of its histology. He also discusses the experimental work carried out with a view of inducing like changes in the vessels of animals. He deals with the physiology of the circulation and gives a full account of the various forms of sphygmomanometer and of the methods of using them, together with a careful consideration of the information obtainable by their use. The etiology of arterio-sclerosis and the clinical features presented by patients with arterio-sclerotic changes in their vessels are considered at length.

Diagnosis and prognosis are dealt with fully in separate chapters. Dr. Warfield lays special stress upon prophylaxis, and counsels "moderation in all things as the keynote to health." He suggests that men and women past the age of 40 years should be urged to submit to a routine physical examination by their medical attendant twice a year. The treatment of arterio-sclerosis and of its consequences is dealt with fully, and some useful general directions are given as regards both the ordering of the life and habits of the patient and the medicinal treatment. A short chapter is devoted to arterio-sclerosis in its relation to life insurance.

We can commend this book as a readable and instructive presentation of a difficult and debatable subject.

Elements of Water Bacteriology, with Special Reference to Sanitary Water Analysis.

By SAMUEL CATE PRESCOTT, Associate Professor of Industrial Microbiology in the Massachusetts Institute of Technology; and CHARLES EDWARD AMORY WINSLOW, Associate Professor of Biology, College of the City of New York, and Curator of Public Health American Museum of Natural History, New York. Third edition, rewritten. First Thousand. London: Chapman and Hall. 1913. Pp. 318. Price 7*s.* 6*d.* net.

DURING the ten years that have elapsed since the appearance of the first edition of this work water bacteriology, so far at least as it relates to examination for sanitary purposes, has undoubtedly advanced, and is on a much sounder, because broader, basis. Lapse of time, which has permitted the accumulation and comparison of large numbers of analyses, is chiefly responsible for this advance. The basis of sanitary water analysis is the correlation of analytical results with the known conditions affecting a water connected with its source, the geological formation from which it is derived, the chances of contamination, or the disasters produced by its use. That this correlation should be of value it is necessary that the analyses should be made by standard methods, and it was the lack of uniformity in this respect that proved the great stumbling block in the early days of bacteriological water examination. The standardisation of methods by the American Public Health Association and the subsequent adoption of a similar standard by English workers constituted a great advance; the standard methods advised form an appendix to this book. Unfortunately this uniformity has been disturbed by the recommendation of the American committee to replace the count of colonies at 20° C. by that at 37° C., a recommendation with which the authors do not agree. They express themselves strongly in favour of the current English practice of making determinations at both temperatures, and give data showing the valuable information which may be gained by contrasting the results so obtained.

Much new information has been incorporated in this edition on the natural history of bacteria in waters of varying purity and under various conditions of temperature and storage. Numerous methods also for the isolation and identification of various pathogenic germs have been elaborated and introduced with more or less successful results, but the essential methods employed in the routine analyses for sanitary purposes have remained very constant, and the changes have been chiefly in the deductions from the results necessitated by fuller knowledge rather than in alterations in the methods employed. The pivot of all sanitary water examination turns on the discovery and identification of B. coli, and a considerable portion of the book is occupied with the methods employed in its isolation and the interpretation to be placed on the number and variety to be found. These questions, especially as to the universality and variety of strains of B. coli, are considered in some detail, but not to the point of obscuring the practical conclusions which may be drawn as to the evidence of fæcal contamination from the presence of bacilli which can produce fermentation with gas production when growing in lactose bile broth at 37° C. The authors do not show that tendency "to set B. coli on a high throne and dance before it" which Professor Gartner deplores. In the United States it appears probable that all the members of the lactose fermenting group of bacilli are evidence of human or animal pollution. The significance of sewage streptococci and of B. enteritidis sporogenes is dealt with and the value and applicability of bacteriological examinations are discussed. Chapters on the bacteriology of sewage and on the examination of shell fish conclude the book. There is a very full bibliography.

This book, which is well printed on good paper, furnishes a very complete and well balanced account of bacteriological water analysis—a subject which has been not a little advanced by the original researches of the authors. To what beneficent results the right application of bacteriology to water analysis may lead we have a remarkable testimony in the condition of the water supply of London to-day, a subject dealt with in a leading article in our issue of Feb. 7th.

Text-book of Paleontology.

Edited by CHARLES R. EASTMAN, A.M., Ph.D., Professor of Paleontology in the University of Pittsburgh and Curator at the Carnegie Museum, Pittsburgh. Adapted from the German of KARL A. VON ZITTEL, late Professor of Geology and Paleontology in the University of Munich. Second edition, revised and enlarged by the editor in collaboration with a large number of specialists. Vol. I. With about 1600 illustrations. London: Macmillan and Co., Limited. 1913. Pp. 839. Price 25s. net.

THE "Grundzuge der Palæontologie," which forms the basis of the present work, was published in 1895. The American translator, Professor Eastman, instead of publishing a strictly literal translation, has modified it in important respects with the author's consent. When a second edition was called for, and in order that an adequate account might be incorporated of the new knowledge that has been gained in recent years, Professor Eastman invited a number of specialists, whose names are given, to collaborate with him in preparing a fresh treatment of the leading groups of invertebrates. The new work, therefore, is a composite production, yet it is in scope and style modelled after the well-known German original.

After defining the subject and its scope the author explains the relations of the subject to geology, physical geography, embryology, and phylogeny; he deals with 'life period' and the extinction of species.

The several phyla are treated in the following order: Protozoa, cœlenterata, vermes, echinodermata, molluscoidea, mollusca, and arthropoda. Naturally the sections on protozoa are short, and the longest chapter is devoted to the foraminifera and a shorter one to the radiolarians. From their constitution the cœlenterata necessarily bulk largely in palæontology, and to them nearly 100 pages are given. Beginning with the porifera, the intensely picturesque and interesting class of sponges is first considered, then the anthozoa and the great group of the corals, the alcyonarians and the graptolites. From their soft texture none are so poorly adapted for preservation in the fossil state as the worms, and therefore a few pages suffice for them. On the other hand, to the echinodermata, with their calcareous plates or calcareous bodies embedded in the integument and sometimes also in the walls of the internal organs—i.e., of the blastoidea, cystoidea, crinoidea, asteroidea, holothurideæ, and echinoidea—the four collaborators on this phylum devote over 170 pages. The phylum of the molluscoidea, including the bryozoa and the brachiopoda, requires over 100 pages for its elucidation, and of these pages to the brachiopoda alone—a very ancient group well represented in the Lower Cambrian and attaining their maximum development in the Silurian and Devonian rocks—nearly 70 pages are devoted none too much, seeing that upwards of 7000 fossil and recent species have been described. The mollusca—which have existed since the earliest recognised advent of life upon the globe—and their progressive modifications afford a most important guide to the successive stages of the evolution of organic life as preserved in the various geological horizons. Their treatment occupies more than a quarter of the whole text. To the arthropoda, including the crustacea, the marine and very ancient trilobites, the ostracoda, cirripedia and their allies the spiders, and the extinct representatives of limulus, myriapods, and insects about 130 pages are given.

This work is an admirable epitome of the palæontology of the invertebrates, excellently printed, and illustrated most lavishly. It should prove invaluable to students of extinct fossil forms and their relations to existing forms of invertebrate life.

LIBRARY TABLE.

Carbon Dioxide Snow. By J. HALL EDWARDS, L.R.C.P. Edin., F.R.S. Edin., Senior Officer in Charge of the X Ray Department, General Hospital, Birmingham. *London: Simpkin, Marshall, Hamilton, Kent and Co.* 1913. Pp. 78. Price 3*s.* 6*d.*—This is a very handy little volume, well written and well illustrated, and considering the popularity of carbon dioxide snow as a local application, one which will be appreciated by members of the profession. A good part of the work is taken up with describing various methods of preparing the snow for use, special attention being given to the one devised and used by the author, which appears to have many advantages. Methods of application and after-treatment are fully described, and in a special section the microscopic changes produced in the tissues are dealt with and illustrated by a series of microphotographs. The list of diseases in which this method of treatment has been found useful is a long one, and full details are given as to the proper method of application in each of them. The book can be cordially recommended.

The Pocket Anatomy. Seventh edition, revised and edited by C. H. FAGGE, M.B., M.S.Lond., F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1914. Pp. 307. Price 3*s.* 6*d.* net.—This useful review manual, the successor of the one-time "Pocket Gray," has been brought up into line with the fourth edition of Cunningham's Text-book of Anatomy, revised by Professor Arthur Robinson. As we said in reviewing the previous edition it is, if properly used, an extremely useful little book. It is pointed out in the preface that the chief innovation in the present edition is the inclusion of those terms from the Basle nomenclature which either have come, or appear to the editor likely to come, into general use.

Genera of British Plants Arranged According to Engler's Syllabus der Pflanzenfamilien (seventh edition, 1912). With the Addition of the Characters of the Genera. By HUMPHREY G. CARTER, M.B., Ch.B. Edin. Cambridge: University Press. 1913. Pp. 121. Price 4*s.* net.—The author, considering that there can be little if any doubt that no other published system of classification of plants rivals Professor Engler's in broad grasp of principle and thorough treatment of complicated detail, notwithstanding that it may be criticised in different points by different specialists, and that the existing lacunæ in our knowledge of different groups leave us far from finality, has compiled this little book to familiarise students of British plants with Engler's system. He has, however, exercised some eclecticism, modifying nomenclature here with a view to secure uniformity of terminations, and adopting other groupings there, as being more rational. The book will prove interesting and useful to students of systematic botany.

MISCELLANEOUS VOLUMES.

IN this section History and Ethics claim our attention with books by Dr. T. J. Walker, August Strindberg, Ethel Snowden, and Sir William Osler.

"That it may please Thee to shew Thy pity upon all prisoners and captives" are words which even now have lost none of their pathos and appeal. The lot of the prisoner is always hard, although it is now in most cases luxury compared to that which prisoners endured when the above-quoted words were written and for some 300 years later. In the year 1814, after the abdication of Napoleon, there were in Britain 67,000 French prisoners, distributed mainly at Dartmoor, Perth, Portsmouth, and Norman Cross, and it is the last-named "depôt" and the life therein which Dr. THOMAS JAMES WALKER describes in his interesting work, *The Depôt for Prisoners of War at Norman Cross, Huntingdonshire, 1796 to 1816.* (London: Constable and Co., Limited. 1913. Pp. 351. Price 10*s.* 6*d.* net.) Both British and French charged each other with ill-treating their respective prisoners, but, as Dr. Walker points out, the practice of the two Governments as regards their own prisoners differed. The British supplied British prisoners in France with clothing, while the French Government absolutely refused to do the same for their countrymen in British prisons. The charges of ill treatment were certainly exaggerated. O'Brien, in Marryat's "Peter Simple," expressed the opinion that "when a man has been cramped up on board a man-of-war, where midshipmen are stowed away like pilchards in a cask, he finds himself quite at liberty in a prison." At Verdun, according to Dr. Walker, the officers seem to have enjoyed a certain liberty, but the common sailors and soldiers were by no means well treated. They were allowed by the French Government only ¾*d.* a day for food, though this pittance was apparently in addition to "a small square piece of bullock's liver, a slice of black bread, and a glass of new brandy." Marryat implies that at Givet the conditions were much more severe than at Verdun, but even so his characters do not complain of real hardships. At Norman Cross the diet seems to have been good if monotonous. With slight variations it consisted of 1 quart of beer, ¾ lb. of beef, 1½ lb. of bread, together with peas or greens on alternate days, and on Saturdays cheese and butter. On Wednesdays and Fridays fish might be substituted for meat. The miseries which certain prisoners undoubtedly endured were due to their gambling away their rations, clothing, and bedding. The most depraved among the prisoners formed a class by themselves, known as Les Misérables. A similar class, known as the Romans, was later evolved at Dartmoor, of whom Dr. Walker quotes the terrible account given by Mr. Basil Thompson in his "Story of Dartmoor Prison." Many of the prisoners occupied themselves in work of a really artistic kind, and Dr. Walker describes and illustrates beautiful articles, such as work-boxes decorated with straw marqueterie or strips of paper, and carvings in bone. The model of the theatre, an illustration of which appears at p. 130, is very elaborate. Many of these works are now in the Peterborough Museum. In addition to the interesting account of the prison life, the book contains valuable appendices dealing with the prison at Verdun, parliamentary papers relating to French prisoners in Britain, and a correspondence concerning the Bishop, or Bishop-designate, of Moulins, who, having been expelled from France, ministered to the prisoners and was allowed by the British Government £240 per annum.——The title *Historical Miniatures* well expresses the scope of AUGUST STRINDBERG's book (London: George Allen and Co. 1913. Pp. 362. Price 5*s.* net), which Mr. CLAUD FIELD has well translated. Strindberg takes a series of historical events, such as the finding of Moses, the deaths of Socrates and Virgil, the flight into Egypt of the Blessed Virgin with the child Christ and St. Joseph, the defeat and death of Roderick the last Gothic King of Spain, the deaths of Nero, Julian, and Attila, of Henry VIII. and Louis XI., to mention only a few, and an episode in the life of Peter the Great. They make interesting reading even if they are not historically accurate, as in one instance is certainly the case. That instance is where Strindberg makes Virgil have a conversation with Horace at the latter's Sabine farm a few days before his death, which Strindberg says occurred at Naples. Now Virgil died at Brundisium within a few days of his landing there on his return from Athens. The most vivid account in the book is the sketch of Peter the Great and the condemnation to death of his son Alexis.

In *The Feminist Movement* (London and Glasgow: Collins' Clear Type Press. Pp. 262. Price 1*s.*) Mrs. Philip Snowden has given us a clear statement of the position of women workers in the society of to-day. Her volume will serve as a simple introduction to a subject which is at the present time so constantly brought to the attention of all those interested in social matters, for it shows plainly the need that is felt by the large number of women engaged in all forms of professions and employment for equality with men "in all those matters of their common humanity where sex does not enter and impose an impassable barrier." She also gives a *résumé* of the methods that have been used by feminists for a century or more to try to bring the attention of the general public to bear on this need. Incidentally Mrs. Snowden points out that a feminist is not of necessity also a suffragist, and that there are many who, while devoting much thought and work to the cause of oppressed women, still do not consider that she will be materially benefited by the grant of a political vote. She insists upon the illogical nature of the methods which have been, and are still being, employed to frustrate the endeavours of women to enter certain professions, and in addition points out that in many instances the law gives an unfair advantage to men as against women, but she omits to mention that by law a man is responsible for the torts of his wife. On the whole, the book gives a fair presentment of the case from the point of view of the feminist.

In his address to Yale students, now published with the title of *A Way of Life* (London: Constable and Co., Limited. 1913. Pp. 62. Price 1*s.* net), Sir WILLIAM OSLER gives us another of those demonstrations in applied philosophy, which on previous occasions have marked him out as a skilled craftsman in moral mechanics. As the master word in medicine for him is work, so the way of life is for him equally simple. It consists in "the practice of living for the day only and for the day's work—life in day-tight compartments"; not, however, in the hedonistic spirit, but because the day of a man's salvation is *now*, and he should "live it earnestly, intently, neither dwelling on the pains or the joys of the past nor anticipating those of the future Keep the body fit—thus helping to keep the mind pure—he says, and avoid slackness by "control of the two principal instincts—biologic habits—the one concerned with the preservation of the individual, the other with the continuance of the species" To this he adds Christ's advice to Nicodemus 'Ye must be born of the spirit," which he interprets as becoming initiated into the fraternity of the great souls that make up the moral radium of the world *A Way of Life* is a good prescription from a wise physician for the health of man's body, spirit, and soul

---

JOURNALS AND MAGAZINES

The Journal of Physiology Edited by J N LANGLEY, Sc D , F R S Vol XLVII , Nos 4 and 5, December, 1913 Cambridge University Press Price 8s —Some Factors which Determine the Blood-flow through the Coronary Circulation, by Josef Markwalder and Ernest H Starling The authors after considering the various methods hitherto used, adopted that of Morawitz, but they used the now well-known "heart lung preparation" obtained from the dog, and they found that Morawitz's method of catheterising the coronary sinus could be applied with ease to this preparation They find that the blood which can be collected in this way amounts to about three fifths of the total blood flowing through the heart wall Moreover, the coronary circulation is intimately dependent on the arterial pressure As to chemical factors, they find that adrenalin causes dilatation of the coronary vessels, a statement made also by previous investigators The addition of CO_2 to the circulating blood so as to increase the CO_2 tension *causes dilatation of the coronary vessels associated* with dilatation of the heart Still more marked than the influence of CO_2 is the effect produced by the total products—i e , metabolites—which accumulate in the blood during asphyxia The authors conclude that the most potent agents which cause dilatation of the coronary vessels are the non volatile metabolites produced by the heart muscle According to the authors, by this means a local mechanism is supplied by which the heart muscle will increase the circulation through itself whenever increased demands are made on its functional activity In asphyxia the circulation through the heart is at its maximum just before the heart fails altogether —Experiments on the Pulmonary Circulation, by H Fühner and E H Starling The heart lung preparation obtained from the dog was used, and the heart volume was recorded by a simple volume recorder already used by Starling and his pupils We have not space in which to describe the technical details but the results obtained show that with a pressure of 80-100 mm Hg in the aorta the pressure in the pulmonary artery of the dog is 14 mm Hg, while at the same time the pressure in the left auricle and in the vena cava inferior is about 7 cm *water* On an average the pulmonary arterial pressure stands to the systemic arterial pressure as 1 6 In asphyxia the failing heart dilates, and the output of the left ventricle gradually diminishes, with a consequent fall in the aortic pressure At the same time the pressure in the pulmonary artery, vena cava, and left auricle rises When the right heart also fails the pressure in the pulmonary artery falls to that in the pulmonary vein and vena cava Adrenalin causes diminished volume of the heart and raises the pressure in the pulmonary artery with a simultaneous fall of pressure in the left auricle These effects on the pulmonary circulation the authors conclude, must be due to a contraction of the lung vessels, since even on the isolated lung perfused with an artificial circulation, adrenalin produces a rise of pressure in the pulmonary artery —Heat Production in Prolonged Contraction of an Isolated Frog's Muscle, by A V Hill This paper is divided into three parts, and is a continuation of the author's already well known researches on muscular heat if such a term is admissible The well known thermopile of Heidenhain is replaced by the author's conical thermophile, which eliminates very largely the errors due to slipping over the junctions The heat production, it appears, is determined by, and is proportional to the length of the fibres during activity Those who are interested in this problem will see the bearing of this question in relation to isotonic and isometric contractions —The Auto Catalysis of Trypsinogen, by H M Vernon, and the Ferments of the Pancreas Part III The Properties of Trypsin, Trypsinogen, and Enterokinase by John Mellanby and V J. Wooley These two papers deal with very complex questions Vernon maintains that recently activated juice may have considerably more activating power than enterokinase itself on the trypsinogen of inactive juice, and he finds that recently activated juice is exceedingly unstable As the summary and conclusions of the second paper occupy nearly two pages, we must refer the reader to the original paper —Lactic Acid Formation, Survival Respiration, and Rigor Mortis in Mammalian Muscle, by W M Fletcher This is a communication of much interest to physiologists, because the author has taken care in estimating the lactic acid formation after excision to discriminate between the white (pale) and red muscles of a limb A red muscle (soleus) shows a much slower rate of survival acid production than the white muscle —The Sugar Consumption in the Surviving Normal and Diabetic Heart by E W H Cruickshank and S W Patterson Cats were used Depancreatised cats became completely diabetic, and they lived for not more than two or three days after complete extirpation of the pancreas Amongst other statements we find "that there may be a diminution in the power c [illegible] " —Studies on Pellagra [illegible] of Maize on the Chemical ([illegible] of Maize meal, by Casimir Funk The author concludes that in maize the localisation of vitamines is closely analogous to that of rice, and it would seem that the vitamines are distributed in the external layers of the grain The influence of diet on growth normal and malignant, in relation to vitamines formed the subject of a paper by the same author published in THE LANCET of Jan 10th, p 98 —The Influence of CO_2 on the Heart in Varying Degrees of Anæsthesia, by E P Cathcart and G H Clark The authors are carrying on a further series of experiments, but as regards the practical aspects of their work they assert that it certainly gives support to the contention that if anæsthesia is to be carried out with any degree of safety it must be deep

The Journal of the East Africa and Uganda Natural History Society (London Longmans Green, and Co Price to non members 5s 4d) —The December issue contains several articles of much interest, especially the one with which the journal opens It is by Mr R B Woosnam, F Z S , game warden for British East Africa, and discusses the question of the Relation of Game Animals to Disease in Africa The writer's conclusion is that there is at present not sufficient scientific evidence to justify the extermination of game as a means of clearing a district of diseases transmitted by blood sucking insects He asks "If wild animals can acquire an immunity in nature and domestic cattle can also acquire immunity, is it not possible that the greatest success may eventually result from an artificially produced immunity? The question has been recently debated in our columns by Professor J L Todd, who opened the discussion (THE LANCET, Nov 22nd 1913, p 1504), Dr Geoffrey D H Carpenter Dr Warrington Yorke, and others —Mr E Wynstone Waters F R S Edin , continues his description of the Organic Cell —Other papers are The Tribes of Tana Valley by Miss A Werner, and the Scientific Classification of Some of the Sea Fishes at Mombasa by Mr R J Cuningham F Z S In a brief note by Mr C M Hobley C M G the editor of the journal, reference is made to the eating of considerable quantities of a soft, grey aluminous rock a kind of steatite imported from India, by Indians and others resident in Mombasa The note has some bibliographical references on the subject of geophagia

---

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC —A public appeal for funds in aid of this institution has been made by Mr James Cantlie in the *Times* The good work done at 22 Chenies street, W C , is familiar to most medical practitioners in and around London, and it would be a public misfortune if this institution which was founded and generously supported by the late Sir Jonathan Hutchinson, should come to a standstill through lack of money The sum urgently needed at the moment is we understand, £5000 and of this £2000 have been advanced by medical men Subscriptions may be sent to Mr Cantlie at 140 Harley street, London, W

BARTHOLOMEW MOSSE AND THE ROTUNDA HOSPITAL.

THE Hôtel Dieu of Paris had a maternity department as far back as the thirteenth century, but it was not until the middle of the eighteenth century that the earliest of these institutions in the British Isles took its rise in the keen sympathy of a medical practitioner with the miseries of the poor. Bartholomew Mosse was the son of an Irish clergyman, the rector of Maryborough, Co. Down, and was born in 1712. After serving his apprenticeship with John Stone, surgeon, of Dublin, he was released from his indentures with a satisfactory certificate in 1733, and at the same time was pronounced "well qualified to practise the art of surgery" after a personal examination by the Surgeon-General, John Nichols. He took medical charge of troops going to Minorca in 1738. He then travelled in "England, France, and Holland, and several other parts of Europe," to perfect himself in surgery and midwifery. Returning to Dublin in 1742 he was admitted a Licentiate of the King and Queen's College of Physicians. On establishing himself in the practice of midwifery, his attention was drawn to the condition of the poorest class of lying-in women, exposed in garrets to cold or in cellars to damp, without attendance, medicine, or even food. The Dublin hospitals had no accommodation for lying-in patients at that time, nor, indeed, had any hospital in the British Isles, for the newly founded Middlesex Hospital did not start its lying-in wards—whence sprang the London Maternity Hospital, now the British Lying-in Hospital—until 1747. Mosse therefore felt that a new kind of hospital devoted to caring for poor women during parturition was needed, and at once set about obtaining the necessary funds to establish such an institution. On Friday, March 15th, 1745, he was enabled to open "an Hospital for Poor Lying-in Women in George's Lane, facing Fade Street," to which the first patient was admitted that very evening. It was a three-storied house of considerable size, containing four beds on each floor, and having an adjoining outbuilding in which were one large and two small wards.

The real difficulty, however, was to find means of adequate support. Mosse faced this by producing plays and oratorios, taking tickets in lotteries, and other entertainments to supplement private benefactions. In this he succeeded, and the new institution, in spite of much opposition and many difficulties, pecuniary and other, justified itself by its results. Mosse was thus emboldened to take the first step towards a more spacious and ambitious scheme, which might well have dismayed anyone with less force of character and perseverance. In August, 1748, he took upon himself the responsibility of a lease for three generations of four acres and one rood of land on the north side of Great Britain-street, whereon to erect a lying-in hospital for at least 150 patients. He first laid out the grounds as public gardens, after the model of the Vauxhall Gardens, London, upon which he expended some £2000 of his own money, walling-in the grounds, erecting an orchestra, concert room, and coffee room, and planting trees and shrubs. Here he organised a series of entertainments with a view to producing a yearly income for the benefit of his charity. His expectations were not disappointed, and in fact to this day the hospital still draws a considerable income from the entertainment rooms and pleasure grounds established by him.

The foundation-stone of the new hospital was laid on July 9th, 1751. In December, 1756, a Royal Charter was granted. Mosse was appointed Master for life, and shortly afterwards a parliamentary grant of £6000 was paid over to the governors, less £180 deducted at the treasury in certain imposts.

Nearly a year later a committee of the Irish House of Commons gave a further grant of £6000 for the completion of the hospital, and a benefaction of £2000 to "Bartholomew Mosse, Master of the said Hospital, as a reward for his great Care and Diligence in Attending the Lying-in Hospital in *George's-Lane*, thirteen years, and superintending the new Hospital in *Great Britain-Street* nine years and a half, by which he hath greatly injured himself in his profession, and hurt his Family in their Circumstances, having never received any reward." Thus, after the overcoming of stupendous difficulties the New Hospital, from designs by the great contemporary architect, Richard Castle, was opened on Dec. 8th, 1757, 12½ years after the establishment, as a private venture, of the original hospital in George's-lane. At the time of the transfer from the old to the new hospital Mosse was able to report that 3975 women had been delivered in the old hospital, with a maternal mortality of 1·10 per cent., "mostly of fever several days after they were safely delivered," at a total cost of £3913 13*s.* 0¾*d.*

Mosse's tenure of office in the new establishment was brief, for he died on Feb. 16th, 1759, in the forty-seventh year of his age, and 13 years and 11 months from the opening of the old hospital in George's-lane, and was succeeded in the mastership by Dr. (later Sir Fielding) Ould.

In Mosse's will he is described as a "Doctor in Physic," and elsewhere as M.D., but no evidence is forthcoming to show where he graduated. His name does not appear on the rolls of any Irish, English, or Scotch University, or on those of Leyden, where so many men of his age took their degree.

In a recent work[1] by Dr. T. Percy C. Kirkpatrick and Dr. Henry Jellett, the present Master of the hospital, from which most of the foregoing information is taken, it is stated: "We find no trace of self-seeking in any of the work done by Mosse. His hospital was everything, and though he claimed honour as its founder, it was only through it and its success that he made any such claim. There is no evidence that he ever used the hospital for his own advantage, either in the way of making money by it, or to advance his professional reputation. Indeed, for the hospital he seems to have sacrificed his entire income and to have abandoned any hope of rising to professional eminence." But little evidence is forthcoming as to his private life, but such as there is seems to proclaim him a good husband and father and a generous friend.

The further history of the hospital and its vicissitudes is recorded at length in Dr. Kirkpatrick's handsome book. Reference, however, may be made here to one particular period in the "sixties," when owing probably to the progressive mortality from puerperal fever, which occurred *pari passu* with the septicæmic condition of surgical wards in hospitals everywhere, there was a marked diminution in the number of patients cared for, which fell to 9181 during the mastership of Dr. McClintock (1854-61), as against 13,741 in the preceding seven years, though the mortality-rate was higher. Under Denham (1861-68) it fell still lower, to 7786. It was at this point that the general outcry against hospitalism reached its culmination, when there were many, as our own columns during that period testify, who questioned whether large hospitals in general, and lying-in hospitals in particular, ought not to be abolished, and Dr. Evory Kennedy, a former Master, in a letter to the board of governors, dated Oct. 28th, 1867, urged "that the time has arrived in which, like all human institutions, progress and changing circumstances have produced such an influence upon it that neither the intentions of the founder, the wants and just rights of the public, nor the claims of humanity, by securing the greatest preservation of life, are accomplished by its instrumentality."

Kennedy's suggestions were negatived, but in the following year he read a paper before the Dublin Obstetrical Society, in which he opened up the whole subject of the hospital treatment of lying-in women. After a discussion lasting 11 nights, while Kennedy's figures for maternal mortality in large and small maternities respectively were not discredited, his suggestions for the abolition of the hospital were not received—fortunately, as it proved, for the sun of Lister's work was rising, and as it became elevated in the heavens it gained power to dissipate the mists that obscured the true significance of the phenomena. Never was the beneficence of hospitals, and particularly of lying-in hospitals, more clearly apprehended than it is at the present day.

Kirkpatrick, M.D., M.R.I.A., Fellow and Registrar of the Royal College of Physicians of Ireland. Edited by Henry Jellett, M.D., F.R.C.P.I., Master of the Hospital. London: Adlard and Co. 1913. Pp. 222. Price, in various bindings, 16s., 18s., 30s., and 32s. The proceeds of the sale will be devoted to the funds of the hospital.

TRACHOMA

And Its Complications in Egypt

BY

A. F. MacCALLAN

DIRECTOR OF OPHTHALMIC HOSPITALS, EGYPT

Price 7s 6d net

PRESS NOTICE

"No one is better qualified than the Director of the Egyptian Ophthalmic Hospitals to instruct us on Trachoma and its management. He has been indefatigable in his efforts to cope with the devastating disease where it is most rife, and he has brought to the work just those qualities which are most essential, though seldom combined in the same individual. With a thorough knowledge of ophthalmology and a sound judgment, he combines exceptional administrative ability, and his efforts are being crowned with the success they deserve. ...... Within the limits of 70 pages Dr. MacCallan has given us the quintessence of the subject, and we congratulate him upon the result."—*Lancet*

TO ADVERTISERS.

The Manager begs to intimate that in order to meet, to some extent, the demand made by Advertisers for "position" pages—in which respect THE LANCET *will still continue to be deficient as compared with most weekly Journals—the position occupied by this and the following page has been created, and will be known as "Preceding Leader."*

Heavy types or heavy blocks will not be eligible for this position, nor can any border rules be used.

The price will be £12 net per page and pro rata, with a minimum space of one-eighth of a column (=1½ in., 15/-), and proceeding by one-eighths (the usual two columns to a page), and consequently there will not be any serial discount.

It will not be practicable to accept any conditions calling for space on either page in particular, or for any precise position on the page, and successive weekly insertions cannot be guaranteed.

NASCENT OXYGEN.

"CONDY'S"

versus

CHOLERA

MILESTONES:

1861.

Condy's Cholera Directions. — "Teaspoonful doses of the Fluid in half a tumbler of water must be given every quarter of an hour, and persevered in even though nausea should result. After the first few doses the stomach will in general come to tolerate the remedy. Enemas, consisting of a tablespoonful of Fluid in half a pint of blood warm water should be administered every half hour."

1866.

Dr. Howard Montgomery, in the MEDICAL TIMES AND GAZETTE, March 10th, 1866, shows the mortality from cholera to be under 5 per cent. when this Fluid is given internally.

1884.

"The only remedy I found to do any real good was Condy's diluted with cold water, and given as a drink freely."—Dr. J. W. Fry, "The Cholera at Saffron Walden."—BRITISH MEDICAL JOURNAL, June 7th, 1884.

1902.

CHOLERA.—"In addition to the usual measures, a high enema of warm water and Condy's solution was given."—Rev. W. J. Webb Anderson, M.B., Ch.B., Wesleyan Mission Hospital, Canton, China.—THE LANCET, September 27th, 1902.

1911.

CHOLERA IN INDIA.—[illegible]

1912.

Dr. E. D. W. Grieg, I.M.S., also reports most important results obtained by this treatment, and Major John Megaw, I.M.S., writes that it "is now so firmly established that it no longer requires special advocacy."—THE LANCET, November 23rd, 1912.

1912.

CHOLERA IN CONSTANTINOPLE.—"Handing cases over to the Turkish authorities meant signing their death warrant. So it was decided that for the future this should not be done, and that all cases should be isolated and not given up as hopeless, and this action proved successful by their cure. This was accomplished by giving internally diluted Condy's and subcutaneous injections of strychnine."—Report by Samuel Osborn, F.R.C.S., Surgeon to the British Red Cross Contingent.—THE LANCET, November 30th, 1912.

The nascent oxygen has a selective affinity for decomposing matter, which it chemically neutralises, while its effects on the stable tissues are entirely benign.

Condy's solution is free from the potassium permanganate which has caused numerous fatal accidents—16 recent Coroners' Inquests.

Proper directions for 150 uses (as attached to every Bottle) forwarded on request.

LONDON: SATURDAY, FEBRUARY 14, 1914.

The Working of the National Insurance Act.

WE publish this week in another column an important memorandum dealing with the case of those persons who desire to make their own arrangements, under *Section 15 (3) of the National* Insurance Act of 1911, with a view to the receipt of medical benefit. The members of the insured public who fall under this category are sharply divided into two classes—those who desire not to select a medical practitioner on the panel, but to make a private contract with a medical man; and those who desire to employ the services of unqualified or unregistered persons. The memorandum takes note with shrewdness and knowledge of the real position, and of the fact that an almost negligible number of persons wish to obtain so-called medical benefit through the administration of persons who are not medical men, and it seems to us unlikely that Insurance Committees will be willing to allow this danger to spread. We trust that our readers will keep a right medical view of affairs steadily before all such members of the public as by their position upon various Insurance Committees are likely to give practical assistance.

It seems to us particularly important that at the present juncture medical men should take every reasonable opportunity of explaining to intelligent laymen the difficulties in which the medical profession has been placed by the extension of contract service, as there is too prevalent a belief that the increase in income, which some practitioners on the panels are receiving, is a panacea for all the ills that they, as well as other practitioners, are experiencing. The situation of the medical profession is distinctly an anxious one in relation to public affairs. We may be certain that it could be paralleled by comparison with that which has obtained at other epochs, for in the nature of things every alteration in the position of the medical practitioner, when it has followed upon new legislation, has been an experiment performed by those who did not know. There is not a series of mysteries involved in our professional life, but it is a life that has to be led before its objective and its social relations, its pleasures and its pains, can be fully understood. The representation of the medical profession in Parliament has always been very small, and when medical members have possessed any hold over the reason of the assembly they have generally owed allegiance to a party, causing their testimony to medicine to be received with reservation; and it is difficult to see how anything else can be expected. Laws which modify the circumstances in which the benefits of medicine are distributed to the community might be more agreeable to the medical profession if they were made from the beginning by medical men, but it is certain that, if by any combination of events such laws were passed, they would be subjected later to great modification, allowing that they were criticised only with justice from the public point of view. The probability is that a fairer general measure in all political departures would, as a rule, be arrived at from the beginning by a Parliament representing general opinion. But the difficulty is that any amendments found necessary by the particular branch of the *public chiefly affected* must be hard to come by, as the onus of proving the need for further legislation would be upon a section of the community with business interests to serve and with only a comparatively small voting strength. Medical men are not here the only class alluded to, but they are the class most likely to suffer from ill-informed law-making because their calling is so delicate a combination of art, business, and philanthropy. Therefore, while they possess no more claim than any other class to frame laws for the community, it is in their case particularly necessary, before legislators attempt to solve problems with the implied assistance of the medical profession, that no endeavours should be spared towards ascertaining what are medical opinions, why they are held, and what is their equitable and logical strength. This precaution was notably absent from the preliminary stages of the National Insurance Bill, and it behoves all medical men to see, when any revision of the existing arrangements comes under the consideration of Parliament, that the medical view is adequately and temperately expressed.

A warning note has been sounded in the *British Medical Journal* to the effect that if the present system of administering medical benefits is found to threaten the financial stability of the Approved Societies new arrangements will have to be made by the Commissioners with the medical profession. The suggestion is, of course, that less money will be paid to practitioners on the panel, a danger ahead which has been already alluded to in these columns. If the Approved Societies obtain the administration of medical benefits, on the plea that only in this way can insurance of the nation against the results of sickness be economically carried on, there will be a return to conditions which have been demonstrated over and over again to be entirely unsatisfactory, and sometimes humiliating to the medical profession. We are drawing attention a long way ahead to a difficulty that is only possible and may not arise, but it is well to be forearmed. The financial standing of some of the Approved Societies will be better known in a little time, while it must be remembered that there is no need for them to hoard the contributions which they receive year by year as stewards. Their members would regard with equanimity the fact that the available money was spent on providing the best form of medical benefits obtainable, and are not likely to support the secretaries and treasurers in any scheme for securing these benefits on the cheap. But it is the officers of the Approved Societies who will be the spokesmen, and the medical profession may find that considerable pressure is being put upon them to return to their former position of service under those officers.

Declining Death-rates.

AMONG the questions raised on the recent publication of the Annual Report of the Medical Officer of the Local Government Board for 1912–13, already reviewed in our columns,[1] that of declining death-rates in England and Wales has received special public attention. In the year 1912 the death-rate in England and Wales from all causes was as low as 13·3 per 1000, the lowest rate yet recorded, a decline of no less than 27 per cent. when compared with the mean yearly rate of a period as recent as 1891–1900. This decline, though perhaps more conspicuous in respect of the mortality of infants and the deaths from certain infectious diseases, has not been limited to these groups; speaking broadly, it may be said that the recent rates of general mortality indicate both an increasing prolongation of life into old age and a greater degree of escape from death throughout all the stages of youth, adolescence, and middle age. Mortality rates, of course, are not necessarily indicative of national healthiness or of the extent to which particular forms of illness are prevalent. With appendicitis, for example, if common indications are to be believed, there has been for some time past an actual and considerable increase in prevalence after all allowance has been made for better diagnosis and for the different names under which this affection was formerly described. The simultaneous development of successful surgical treatment, however, prevents the official mortality returns from giving any real clue to the extent to which the disease prevails or from showing how fast it is increasing. Or, to take another illustration, we might refer to the large amount of temporary invalidism that is apparently being caused at the present time by sudden attacks of "gastric" illness attributed to the infection of influenza. As in the case of appendicitis, the examination of mortality figures does not help towards general or local investigation of the prevalence or causation of a widespread illness of this nature. While, however, the distinction between reduction of mortality and decline in sickness is an obvious one and needs to be remembered, it is difficult not to believe that the general fall in mortality as a whole connotes diminishing invalidity and increased healthiness. In the case of infants and children the association is particularly close, and the considerable fall in the death-rates at young ages in recent years is no doubt to be connected with the greater consideration now given to the individual life, with the early detection and treatment of ailments which in former years would have been neglected until they became formidable, and in large measure also with the greater healthiness which has resulted from the improved conditions of nurture and environment of children.

As said above, the mortality figures for most of the infectious diseases in 1912 show striking reductions when compared with the average experience of 1891-1900. The decline in the case of measles is 16 per cent.; from scarlet fever 66 per cent.; from whooping-cough 40 per cent.; from diphtheria and croup 57 per cent.; and from enteric fever 75 per cent. The mortality from typhus is now practically nothing, and in the absence of any considerable epidemic of small-pox the death-rate from that disease is at present negligible. The chief causes which have led to these reductions are not identical in the case of each disease. Those who have special experience of diphtheria, we believe, would ascribe the fall rather to the curative power and increased use of antitoxin than to any decrease in its prevalence or change in its intrinsic severity. The fall in the scarlet fever rate is held to be attributable only in a minor degree to improved treatment or to lessened prevalence, and is set down to a distinct change in its clinical character, associated with a much milder type than that met with 20 or 30 years ago. By contrast the great reduction of enteric fever mortality is undoubtedly due to a definitely lessened prevalence, which has followed the purification of public water-supplies, prevention of food contamination, and other sanitary measures. Nevertheless, it seems possible that in some at least of the infectious diseases common factors may be steadily at work to diminish virulence, including possibly the much greater intercommunication of the present day which may promote the spread of mild or unrecognisable infections which confer some degree of immunity.

In the case of tuberculosis the mortality from all forms in 1912 is 32 per cent. less, and from pulmonary tuberculosis 25 per cent. less than the average rate for 1891–1900. In respect of phthisis the fall continues the steady decline which has been taking place since 1853, and has increased in its rate of fall since 1867, when the deaths ascribed to phthisis were relatively more than twice as many as they are now. The decrease which has set in during the last six or seven years in tuberculous diseases other than phthisis is noteworthy, as previously these rates tended to be stationary. Notwithstanding the immense amount of study which has been given to this disease, it is almost impossible to assign values to the different causes which have led to the steady and continuous decline in the mortality from tuberculosis. The effects of migration, "urbanisation," exposure to infection, race, and heredity, the relation of human and bovine tuberculosis, and the possible acquisition of immunity by infection in early life are a few among the considerations to be taken into account. Readers of our issue of Jan. 31st will have noted in Dr. W. CECIL BOSANQUET'S lecture on "Tuberculosis as an Infective Disease," evidence both of the difficulties of the problem and of the helpfulness of the conspectus of the present position which is there given. It would probably be difficult to exaggerate the importance of the part played by changes in the social condition of the population of this country during the past 40 or 50 years, including alterations in housing and diet, in reducing the prevalence and fatality of tuberculosis. In the latter part of this period also the increase of medical knowledge and the improvements made in treatment must have had a great effect in the same direction. Although many years have elapsed since sanitarians began to press for more light and air about dwellings and the prevention of atmospheric impurity, it is not so long since current medical treatment of consumptive patients still permitted the respirator, the shut bedroom, and other devices which are now regarded as disastrous. A further acceleration of the rate of decline in tuberculosis mortality by the preventive and curative measures which the public authorities have now begun so energetically to undertake is one of the most hopeful prospects of medical science, and the fact that there are still over 35,000 deaths annually from phthisis alone in England and Wales is enough to show what remains to be achieved.

The Notification of Ophthalmia Neonatorum.

THE Local Government Board, by an Order issued at the end of last week, has made ophthalmia neonatorum a notifiable disease. Heretofore notification of this disease has only been compulsory in those administrative areas in which the Local Government Board had sanctioned the procedure. In the year 1912 there were 216 sanitary districts which had availed themselves of this opportunity, and during last year this number was considerably augmented. Since March, 1911, by an Order extending the provisions of Section 55 of the Public Health (London) Act the notification of ophthalmia neonatorum by medical practitioners and midwives has been made compulsory, and during that year 673 cases were notified, a number which represents an incidence of 0·843 per 100 births. During the year 1912 approximately 700 cases were notified in London, and of these 5 cases resulted in complete blindness in one or both eyes. At the meeting of the British Medical Association held in London in 1910 one of the subjects for discussion was the administrative control of ophthalmia neonatorum, and in opening this discussion Dr. GEORGE REID, the medical officer of health of the county of Staffordshire, made out a very strong case for the compulsory notification of the disease and for its free treatment at the public expense. He claimed that the cost of educating a blind child was approximately £500, while the cost of educating a child who had ordinary vision was no more than £50. As the cost of education usually fell on the public authority, it was clear from the number of cases of blindness which annually resulted from the disease that there would be a handsome offset to the expenditure incurred by prophylaxis and treatment if any cases of blindness were thereby prevented.

The experience of London, Liverpool, and Staffordshire prove that the incidence of blindness is very small if cases of ophthalmia neonatorum are taken in hand sufficiently early and are treated in accordance with approved methods. Whether prophylaxis should go the length of instilling a drop of protargol solution into the eye of every new-born infant is a question which still vexes the minds of some authorities, but there can be no doubt that all cases of ophthalmia with a purulent discharge should be treated drastically under medical supervision from the start. It has been calculated that the average cost of treating such cases in Staffordshire—a cost which includes in many cases the long-continued services of fully trained nurses—is about £3 1s. 6*d*.

The action which the Local Government Board has taken in making this serious infective disease compulsorily notifiable in every sanitary district in England and Wales will be strongly commended by all public health authorities, and it is particularly gratifying that the definition of the complaint—namely, as "ophthalmia with a purulent discharge from the eyes of an infant commencing within 21 days from the date of its birth"—leaves no loophole for prevarication or evasion in those cases in which the bacillus of Neisser has not been, or cannot be, demonstrated by bacteriological methods. Although probably the consequences are not serious, there can be no doubt that pathological admissions, such as that which the notification of ophthalmia neonatorum would entail, must be somewhat hard to come by, if such admissions in any way serve as *primâ facie* evidence of unskilful practice. Such cases have, however, been known to occur, the responsible parties sheltering themselves under the plea that the discharge from the eyes, though purulent, was not due to the gonococcus.

The Royal Commission on Venereal Disease which is now sitting will certainly have to pronounce on the advisability or the reverse of the compulsory notification of syphilis and gonorrhœa, and more than one of the Government departments has already been memorialised to include both diseases among the number of those notifiable. The argument that the compulsory notification of venereal disease might defeat its own purpose by delaying or interfering with medical treatment through the fear of disclosure of the nature of the complaint may or may not be sound, but it seems that in the compulsory notification of ophthalmia neonatorum we have a most effective means of acquiring a knowledge of the incidence of at least one of these diseases without any of the objections to which the direct notification of the responsible parties might possibly conduce.

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

THE Departmental Committee on the University of London, appointed to recommend, after consultation with the bodies and persons concerned, the specific arrangements and provisions which may be immediately adopted in order that effect may be given to the scheme of the Report of the Royal Commission on University Education in London, have now resumed their sittings. The committee have invited the observations of the Senate upon the proposals of the recent Royal Commission with regard to the admission of external students to the examinations of the University for degrees, regard being had to the principles upon which the report is based. The committee would also be glad to receive not later than March 14th reasoned statements bearing upon these proposals from other bodies and persons concerned.

MEDICINE AND POLITICS IN ITALY.

"TO-DAY the extension of the suffrage," writes an Italian correspondent, "has enlarged the electorate from about 3,000,000 to 8,000,000, and of these latter a large proportion are analfabeti, that is, can neither read nor write. There are questions before the country of even greater urgency than the riveting of Italy's foothold on the Southern Mediterranean seaboard, and these are education and, in closest connexion with it, the public health. That so large a proportion of the electors should be 'analfabeti' is a reproach to Italy and her legislators which cannot be too soon wiped out—a state of things appealing more sensibly to her *amour propre* than colonial extension or even military prestige. Not less urgent and not less vital for her rehabilitation and self-respect is the improvement of her hygiene, a necessity now more than ever borne in upon her, and explaining not only the large proportion of medical men among the candidates at the late elections, but the recent accession of distinguished consultants to her Upper Chamber. The Italian Senate, indeed, stands pre-eminent throughout Christendom for the number of physicians and surgeons it can boast of—men who, while professional men devoted to their calling, have not forgotten that they are also citizens, citizens, moreover, of a nationality comparatively new in the State system of Europe. Numerous as they already were in the Senate, the Premier has added, as your Italian correspondent has already reported, still more to their strength, and in the 29 new nominations has made three who are, each of them, eminent in medical practice and research. Dr. Ettore Marchiafava, whose name occurred so frequently in the consultations held during the Pope's grave illness last spring, is one of these, and not only the profession but the public at large are at one in recognising the justice of his promotion to a legislature before which the question of medical education and, with it, those of scientific research and hygiene, press forward for consideration and solution. His record as professor of comparative anatomy at the Sapienza as well as his intervention in the crusade against malaria are of themselves a "title-deed" to the honour just conferred on him. The second on the list, Dr. Carlo Forlanini, has an equally valid claim to the distinction of Senator. Born some 66 years ago at Milan, and professor of physiology and clinical medicine at the Lombard University (Pavia), he has won an authoritative position in the domain of public health, particularly in the legislation against tuberculosis, while his clinique has been frequented by students from other seats of learning for his special mode of dealing with pneumothorax described some three years ago in THE LANCET. The third consultant now promoted to the Upper Chamber is Dr. Gerolamo Gatti, who holds with much acceptance the chair of surgical pathology in the Florentine Institute, and, while devoted to clinical research and professional teaching, has found time to study social questions, particularly those relating to the condition, moral and physical, of the agricultural labourer. A convinced Socialist, though not enrolled in any of its numerous sects—being, indeed, a trenchant critic of the Marxist dogma and practice—he is a representative of the interests of the *democrazia rurale*, beginning with the physical development of the children and directing, *ad hoc*, the Hospital for Surgical Pædiatry in Florence. Younger than the majority of his professional brethren in the Senate, he adds to their experience an energy all his own and will contribute effectively to the consummation of that policy, known as socio-medical, which is destined for many years to form an important factor in Italy's legislation."

MODERN LEPROSY.

SANITARY authorities in various parts of Europe are now occupying themselves in trying to check the spread of leprosy, recently believed to be almost extinct. The incidence of the disease is increasing surely though slowly and precautions can no longer be neglected. In France especially, as appears in our Paris correspondent's letter (p. 491), considerable disquietude prevails, and legislation in the matter is being invoked. A curious study containing certain considerations, interesting at least as hypotheses, has been recently published by Dr. Blendeau, who holds that the disease had existed in Europe before the Crusades, but had become attenuated by a sort of racial vaccination. In Palestine the Crusaders came into contact with another variety of the same microbe, for which they afforded an entirely new culture medium. This was the grand leprosy of the Middle Ages, brought back by the Crusaders to their own lands, where the oriental bacillus caused the most frightful ravages. Then, in a similar manner, its pathogenic power also diminished, and Europeans once again became refractory to the disease. The present reintroduction of leprosy is probably due to the more frequent and rapid communication in recent decades with the Far East. About 40 years ago the Chinese carried leprosy into Polynesia, where it had been up to that time unknown. The natives, who afforded a new field for it, contracted it rapidly and contaminated the whites, who in their turn brought it back to Europe. This Polynesian bacillus appears to be of a dangerous character, for now Europeans who have become leprous there and have returned to Europe convey leprosy to European countries of so virulent and contagious a character as to call for vigilant and strenuous protective measures.

TUBERCULOUS PERITONITIS IN GIRLS SIMULATING DISEASE IN THE INTERNAL GENITAL ORGANS.

IN the *Australasian Medical Gazette* of Dec. 13th, 1913, Mr. A. J. Nyulasy has reported two interesting cases of a rare form of tuberculous peritonitis commencing in the Fallopian tubes which simulated other diseases. Both occurred in girls, aged 17 years, and in the first case neither the family history nor the appearance of the patient suggested tuberculosis. A healthy looking girl was admitted into the Perth Public Hospital complaining of pain in the iliac fossæ which was of several years' duration and increased during menstruation. With the onset of menstruation, five years before, leucorrhœa began and had continued ever since. The abdomen was much enlarged, and dulness extended upwards above the umbilicus and higher on the left side than the right. The dull area was indefinitely fluctuant. The hymen was unruptured, and the uterus was displaced to the right. A tense irregular mass was felt in Douglas's pouch, and pressure on the abdomen above was transmitted to the examining finger. The temperature was somewhat raised, but the general condition was good. Ovarian cyst was suggested. On opening the abdomen the omentum was found greatly thickened and adherent to the abdominal wall, and forming the anterior wall of a fluctuating "cyst," which was tapped, and yielded about six pints of straw-coloured fluid. On further separating the omentum from the abdominal wall tubercles were seen thickly studding it and the parietal peritoneum. The anterior wall of the "cyst" was found to consist of thickened omentum and a layer of fibrinous material. Posteriorly the cyst wall was formed by the rectum and intestines. The fibrinous material was removed with difficulty, and the involved area was then seen to be studded with tubercles, many of which were caseous and broken. The Fallopian tubes were thickened and enlarged, especially at the outer ends, which were fully two inches across, and they contained much fluid caseous matter. The ovaries appeared to be normal. Both tubes and the greater part of the omentum were removed, caseous matter was cleared away, the pelvis was filled with saline solution, and the wound was closed without drainage. During convalescence a tuberculous sinus formed in the upper end of the abdominal wound and was scraped with success. Two years later the patient was in good health. In the second case a girl, aged 17 years, was admitted complaining of abdominal pain of two months' duration, the hæmorrhage having continued since the last menstrual period five weeks previously. She had the delicate pink colouring and fine hair suggestive of tuberculosis, but was not badly nourished and the family history was good. The lower abdomen was tender and somewhat distended. The hymen was unruptured and a rather firm mass was felt in Douglas's pouch, apparently covering an anteverted uterus. On opening the abdomen the omentum was found adherent to the parietes and the parts beneath. When it was separated bright blood appeared in quantity, suggesting ectopic gestation. When the blood had been mopped up grey translucent tubercles were seen studding the parietal peritoneum, omentum, and a mass of intestines densely adherent to the uterus, tubes, and broad ligaments. The adherent intestines were roughened, congested, and sodden-looking. Separation of the adhesions was thus not only difficult but dangerous. The uterus could not be brought clearly into view, but was felt to be small and irregular in consistence. A way was at length made behind it down into Douglas's pouch, where the left tube was felt enlarged and densely adherent to the broad ligament beneath adherent intestines. It was considered unjustifiable further to attempt removal of this tube. The right tube was found much enlarged and very adherent to the broad ligament and to overlying intestines. The end of the tube could be felt in Douglas's pouch, and on separating it some ounces of pale yellow pus oozed up. When this had been mopped out the free end of the tube and an apparently healthy ovary could be partly brought into view. On account of the friable condition of the involved intestines and the extent of the adhesions it was deemed inadvisable to proceed further in an attempt at salpingectomy. The operation area was dried out, a pint of saline solution was run in, and the wound was closed without drainage. The patient was placed in Fowler's position and saline solution was given per rectum. In a couple of days she was taken into the open air and did remarkably well. When discharged some weeks later she had put on weight and was looking and feeling well.

COÖRDINATION AMONG LONDON HEALTH ASSOCIATIONS.

As the result of a conference held at the Mansion House in July of the year before last, at which representatives of Government departments, public authorities, and voluntary agencies concerned with the health of the metropolis were present, a body known as the "Central Health Committee (Voluntary) for London" was constituted. This committee consists of 23 members, and meets in the offices of the Local Government Board. As a result of its labours a report, which contains brief particulars of some of the voluntary societies carrying on health work in London, has been drawn up, and this report has now been printed and circulated by the Local Government Board. Copies of it have been sent to the mayor of every metropolitan borough and the chairman of every metropolitan board of guardians. An official letter which accompanies the report emphasises the advantages to be derived from coöperation between local authorities and voluntary workers. It is suggested that in each borough the mayor a [illegible] convene [illegible] some sc [illegible] importance and value of mutual understanding and assistance on the part of voluntary societies and local health authorities are unquestionable, for overlapping is thus prevented, and unstopped gaps are brought to notice. It is therefore gratifying to find that the Local Government Board is cognisant of the need for coördination and prepared to encourage it. The actual report itself, which stimulated the Board to suggest that the voluntary workers should undertake the organisation involved, is a somewhat disappointing document. It does not pretend to be exhaustive, and is in fact far from complete. It is said to be the result of much work, but there is no internal evidence of anything of the sort. Its publication by the Local Government Board is a proof that the value of coöperation in health work is officially recognised; but it is not the beginning of such coöperation. As a matter of fact, local voluntary agencies and local branches of central societies do actually coöperate with one another and with the borough health authorities. The extent of such inter-communication varies in different boroughs and is seldom quite as great as it might be with advantage, but it is nowhere non-existent. While prepared to give due credit to every effort made to increase desirable coördination in health work we are not especially sanguine that progress will be much stimulated either by the letter from the Local Government Board to the metropolitan mayors or by the incomplete compilation which it covers.

THE RÔLE OF SYPHILIS IN MENTAL DEFICIENCY AND EPILEPSY.

IT is well that the attention of the medical profession should be directed to a recent paper in the *Journal of Mental Science*[1] by Dr. Kate Fraser, assistant medical officer, Govan school board, and Dr. H. Ferguson Watson, medical officer of H.M. prison, Peterhead, lately assistant medical officer, Renfrew District Asylum. In pre-Wassermann days syphilis was regarded as a relatively unimportant factor in the production of mental deficiency. Shuttleworth, for instance (1888), examined 1000 cases by clinical methods only, and found evidence of syphilis in ten. Even in the new edition of Allbutt and Rolleston's "System" (1910) Shuttleworth and Fletcher Beach state they could trace inherited syphilis in only 1·17 per cent. of their cases. With the Wassermann reaction to help us, however, many cases of mental deficiency have been shown to give a positive result which present no clinical symptoms or signs of syphilis. Dr. Fraser and Dr. Watson are the first, we believe, to carry out a general systematic inquiry on this subject in this country, and they emphasise the necessity in all cases of obtaining the family history, making a clinical examination, and performing the Wassermann test. The blood-sera of 99 mentally defective and epileptic children, mainly attending special schools, were tested by Dr. Fraser. A positive reaction was obtained in 44·9 per cent. of 89 cases of mental defect. Of 34 cases of epilepsy among the number, presenting varying degrees of mental defect, positive results were obtained in 15; 15 more gave a negative reaction. Members of the families in 13 of these negative cases were also tested by the Wassermann reaction, and in no fewer than eight instances the test was positive in one or other member. One or two illustrations of the importance of this finding may be given. The serum of a defective girl gave a negative reaction; the mother was a well-developed, healthy woman, who said she had never had a day's illness in her life, nevertheless her blood gave a positive Wassermann reaction. A mentally defective boy and his father both gave negative results, while the boy's twin sister and his mother both gave positive results. In one family a boy and two girls were examples of lesser degrees of mental deficiency, but their sera, tested by Wassermann's methods, were negative. Their mother complained of loss of memory, and was dirty and untidy. Her serum was positive. It should further be noted that only in eight of all the positive cases were stigmata of congenital syphilis present. Dr. Watson examined the serum in 105 cases of mental deficiency, all but six of whom were under 15 years of age. Only 13·4 per cent. showed stigmata, yet no fewer than 51, or 48·5 per cent., gave a positive reaction. Both investigators employed the same technique, and in their paper they demonstrate the extreme care with which their results were tested. As a matter of fact the results obtained by the two independent investigations are practically identical. Out of 204 cases syphilitic infection was present in 123, or 60 per cent. The conclusions drawn by the authors are expressed somewhat as follows: syphilis is the causative factor in more than 50 per cent. of cases of mental deficiency, of whatever degree of severity. Investigation of the families in which defective children appear shows that syphilis is associated with a still higher percentage of cases than is ascertained by the examination of the patients alone. Only a very small percentage of the cases under discussion show external evidence of congenital syphilis, even where the family history and the examination of other members of the family afford practically conclusive evidence of the existence of syphilitic infection. The results of the authors show a larger proportion of positive cases than those of any previous observer. It is important to bear in mind, however, that, as has been demonstrated by others, the percentage of positive reactions diminishes rapidly after the sixteenth year; the cases investigated by Dr. Fraser and Dr. Watson were mainly between 1 month and 14 years of age. The paper is a valuable contribution to the study of the etiology of feeble-mindedness, and it appreciably widens the field of research.

A RARE COMPLICATION OF PHIMOSIS.

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Jan. 25th Dr. H. Griewank has reported a rare complication of phimosis which occurred in a native of Senegal, who came under observation at the age of 25 years. About the age of 10 years he was circumcised by some native operator, according to the custom of the country. According to the patient the operation was incompletely performed and the preputial stump became inflamed and considerably enlarged, while at the same time the urine was passed with more and more difficulty. At each micturition the urine formed a tumour which was slowly emptied through a punctiform orifice. In the end the preputial pouch thus formed was never completely emptied, and a rounded tumour formed at the end of the penis and gradually enlarged. On examination a spherical tumour of the size of the fœtal head at term hung from the end of the penis. On its surface was a well-marked venous plexus. On its right side was a small orifice from which drops of urine, with a strongly ammoniacal odour, constantly flowed. The penis was slightly enlarged. On palpation the tumour was tender and resistant, and on percussion it was dull. On the left side the inguinal glands could be felt. Catheterism of the urinary orifice with the smallest instrument was impossible. Exploratory puncture with a Pravaz syringe yielded turbid urine with a strong ammoniacal odour, and the sensation of the needle striking against a hard body, such as a calculus, was felt. The general health was excellent. Almost complete preputial atresia, stagnation of urine between the prepuce and glans, decomposition, and formation of calculi were diagnosed. An incision was made at the most dependent part of the tumour; it passed through greatly hypertrophied and chronically inflamed tissue about 3 centimetres thick. Numerous small calculi of a yellowish-white colour were found filling the whole space between the prepuce and glans. They were removed, circumcision was performed, and the case ran the ordinary course. The calculi removed weighed 540 grammes. They were generally in the form of a *calotte*, convex on one side and concave on the other. The largest were of the size of a small haricot bean and weighed 40 centigrammes; the smallest were of the size of a lentil and weighed about 20 centigrammes. They almost all contained a hard nucleus, around which was a more friable deposit. Chemical analysis showed that they were composed of calcium and ammonium-magnesium phosphates.

[1] October, 1913.

ACCIDENTS FOLLOWING THE TRANSFUSION OF BLOOD.

IT is generally supposed that transfusion of human blood is an operation without ill-effects, but a considerable number of cases in which hæmolysis or agglutination of the donor's blood corpuscles occurred have been recorded, and some have been fatal. Delirium, jaundice, and, in severe cases, hæmoglobinuria were the symptoms. In the *Journal of the American Medical Association* of Dec. 13th, 1913, Dr. R. Ottenberg and Dr. D. J. Kaliski have published an important paper, in which they show the value of preliminary blood examination in avoiding accidents. Hæmolysis of one human blood by another is a pathological phenomenon which was thought to be especially characteristic of cancer and tuberculosis, but is now known to occur in a great variety of diseases. By means of a modified Wright's capillary pipette Dr. Ottenberg and Dr. Kaliski examined the blood of 128 patients and found it to be hæmolytic for several prospective donors in 17. The diseases in which this occurred were purpura hæmorrhagica, carcinoma of the stomach, carcinoma of the rectum, lymphatic leukæmia, pernicious anæmia, chronic osteomyelitis (due to staphylococcus aureus), and pelvic abscess. In all except two cases the patients' serums were hæmolytic with only some of the prospective donors' blood. In two cases, on account of the desperate condition of the patient, hæmolytic transfusion had to be ventured. In one the disease was pernicious anæmia. The serum of the patient was agglutinative and weakly hæmolytic to the cells of the donor. The transfusion was followed by intense hæmaturia, which lasted 24 hours, during which the hæmoglobin fell from 34 to 31 per cent. instead of rising, as almost invariably occurred in other cases. In spite of the loss of the transfused blood the transfusion apparently had a favourable influence, as the patient improved slowly but steadily during the following month. He returned to hospital eight months later and a second transfusion was done from a donor whose blood was not agglutinated or hæmolysed by the patient's serum. This transfusion was successful; the patient was greatly improved and life was prolonged for a year and a half. In the other case (acute lymphatic leukæmia) the patient's serum sharply agglutinated the donor's cells, but only slightly laked them after three and a half hours in the thermostat. No hæmoglobinuria followed the transfusion, but blood smears showed phagocytosis of red cells by leucocytes in the circulating blood. The patient died 42 hours after the transfusion. Jaundice occurred in only one case and was slight and transient. The absence of hæmoglobinuria in over 100 cases in which hæmolytic donors were excluded shows the value of blood examination. Agglutination, unlike hæmolysis, is not a pathological phenomenon, but occurs between normal human bloods. All human beings can be divided into four permanent hereditary groups sharply separated by agglutinative reactions. When the blood of two persons belonging to the same group is mixed no agglutination occurs. When the blood of two persons of different groups is mixed agglutination either of one by the other or of each by the other always occurs. Human iso-agglutinins are present only in small quantities and can be absorbed by a small number of susceptible cells. When the serum of the donor is agglutinative to the cells of the patient, it will be so diluted on transfusion that little, if any, agglutination will result. When the patient's serum is agglutinative towards the donor's cells the conditions are more favourable to agglutination, but even here it is probable that only exceptionally can massive clumps of agglutinated cells be formed, such as are seen in the test-tube. Only in these cases has phagocytosis of the cells in the circulating blood been observed. Dr. Ottenberg and Dr. Kaliski have seen three transfusions in which the serum of the patient was agglutinative to the cells of the donor, and in two of these the serum was slightly hæmolytic. One was the case of lymphatic leukæmia referred to above. Another was a case of pernicious anæmia. Blood smears made after the transfusion showed phagocytosis of red corpuscles by polynuclear leucocytes. No urine was passed after the transfusion, and death occurred eight hours later. The necropsy revealed extensive phagocytosis of the red corpuscles in the spleen and lymph nodes. Agglutination need not be regarded as a contraindication to transfusion, but non-agglutinative donors should be chosen if possible. There is an important corollary not given by Dr. Ottenberg and Dr. Kaliski. As the principal danger of transfusion is hæmolysis, and as this occurs only in disease, normal blood can be safely transfused in a case of hæmorrhage.

TUBERCULOUS RHEUMATISM.

THE relation between tuberculosis and rheumatism is a topic which has lately been discussed in many quarters. In THE LANCET for Jan. 3rd we published an interesting case of tuberculous rheumatism recorded by Dr. Nathan Raw, whose investigations, including inoculation experiments on guinea-pigs, clearly proved the tuberculous nature of the rheumatism. Some writers are apt to label polyarthritis as tuberculous when it occurs in the subjects of pulmonary and other forms of tuberculosis. Theirs is the view that various manifestations should, as far as possible, be "hung on one peg," instead of being attributed to more than one primary factor. Dr. Raw considers tuberculous rheumatism very rare. Professor Poncet and his school consider it very common. Several cases have lately been published in which injections of tuberculin provoked great pain and swelling in many joints already the seat of rheumatism, which has accordingly been regarded as tuberculous. At a recent meeting of the Medicinske Selskab of Christiania Professor Peter Holst discussed the difficulties of correlating tuberculosis with polyarthritis. In 27 cases of chronic and subchronic arthritis he punctured the joints, and injected the fluid thus obtained into guinea-pigs, or he examined it microscopically. None of the nine guinea-pigs thus treated developed tuberculosis. Inoculation into guinea-pigs of glands excised from the neighbourhood of the swollen joints also gave a negative result. Diagnostic injections of tuberculin provoked in almost all these patients fever and general malaise, but with one exception there was no exacerbation of the arthritis. The one patient whose arthritis was affected by 5 milligrammes of tuberculin was a girl, aged 17, whose chronic polyarticular rheumatism had begun as an acute rheumatism. The tuberculin induced fever and the formation of a ganglion over one ankle. Fluid withdrawn from the ganglion contained lymphocytes and was injected into a guinea-pig, which did not develop tuberculosis. While the fluid withdrawn from the joints in this case contained no other cells than lymphocytes, the fluid withdrawn in all the other cases contained numerous polynuclear neutrophil leucocytes and an occasional macrophage. Speaking at the same meeting Dr. Tillisch, of Grefsen Sanatorium, reported four cases of subacute polyarthritis with effusion which he had observed among his consumptive patients. The condition resembled closely that of acute rheumatism, and in one case disappeared after a course of tuberculin. In two other cases swellings of the ankles disappeared spontaneously. In the fourth case the disappearance of the arthritis was followed by purpura hæmorrhagica and nephritis. Dr. Tillisch finds salicylates give relief in such cases, but on this point he stands practically alone. Menzer and many other writers consider salicylates and similar drugs objectionable, as they may mask the condition which requires vigorous treatment with vaccines, including tuberculin. Recent work on tuberculous rheumatism leaves the impression that our knowledge in this field is exceedingly limited.

ETHER IN CASES OF PURULENT PERITONITIS.

ON previous occasions[1] reference has been made in our columns to the intra-abdominal use of ether in France by Dr. Souligoux, Dr. Morestin, and others. Dr. Morestin has systematically used ether in doses of two to four ounces in all cases of purulent peritonitis. All accessible parts of the intestine are first washed with ether, and two to four ounces of pure ether are then poured into the abdominal cavity and left to evaporate. Of course, all primary sources of infection, such as the appendix and so forth, are treated, and if accessible removed. In 31 cases, some of which were apparently utterly hopeless, the results exceeded all expectation. Dr. Morestin speaks favourably of the simplicity of the procedure and the rapid improvement of the patients. He suggests that the ether stimulates the intestinal circulation and acts antiseptically. Dr. Souligoux and Dr. Témoin have each reported two apparently hopeless cases of perforative peritonitis which terminated in recovery. To these Dr. Jeanneret, in a recent number of the *Revue Médicale de la Suisse Romande*, adds the following case treated by him in an Alpine health resort, removal to a hospital being impossible. A boy, aged 7, was attacked by appendicitis on July 20th, 1913. Perforation occurred on July 22nd. Pulse 160, temperature 103° F. Two surgeons having declined to interfere surgically, by July 23rd collapse rapidly increased. The tongue was dry and coated black, and the boy was comatose. The temperature sank from 103° to 96°, while the pulse rose to 180. At 8 P.M. surgical intervention was practised *in extremis*. Laparotomy revealed generalised peritonitis proceeding from a perforated and gangrenous appendix. The appendix was removed and the abdomen drained. Two ounces of ether were poured through the drain into the lower part of the abdomen. The pulse fell to 135, and a slight rise of temperature from 96° occurred. There was no vomiting, and the boy passed a good night. Next day saline transfusion was administered, one pint in the morning and half a pint in the evening. The pulse was now 130, the temperature from 100·5° to 101°. On July 26th the temperature was 98°, the pulse 80, and the boy had his first normal movement of the bowels. Slow improvement took place during the next eight days; then serious symptoms again supervened, the temperature rising to 102° and the pulse to 130–140. Another injection of two ounces of ether was given through a drainage-tube. After this recovery was rapid and definite, and in six weeks the boy was running about again. It would seem that the rapid subsidence of serious symptoms on two occasions in this patient justifies a hopeful attitude in regard to this method of treatment, sufficient at least to justify its more widespread trial.

THE STUDY OF NEW GROWTHS.

WE have received the November–December number of a bi-monthly periodical entitled *Tumori*,[1] published under the superintendence of G. Fichera at Rome. Among other interesting articles there are two which call for special notice. One is an account of a case of cancer of the stomach treated by means of autolytic fœtal products by Dr. A. Bazzocchi at the hospital at Ronciglione. The patient was a woman, aged 48, suffering from abdominal pain after food and wasting. There was a pyloric tumour and dilatation of the stomach with enlargement of the supraclavicular glands on the left side. Extract of fœtal organs, thyroid, thymus, and spleen, was injected on four successive days, and improvement in the patient's condition was at once noticed. A year afterwards her weight had increased from 62 to 71⅓ kg., no trace of the pyloric tumour existed, and the patient was in florid health. The supraclavicular glands which had been excised showed epithelial nests. The second paper is a contribution to the study of hæmo-angioma of the mamma by Dr. G. Marangoni, of the Hospital at Padua. This kind of tumour is of extreme rarity, and the case reported is interesting on account of the clearness with which the peripheral development of the neoplasm can be followed.

THE Milroy lectures at the Royal College of Physicians of London will be given this year by Dr. F. Shufflebotham, of Newcastle-under-Lyme, who will lecture upon the Hygienic Aspect of the

[1] Tumori, Archivio bimestrale fondato da G. Fichera, Anno iii., Fasc. iii., December, 1913, Roma.

Coal-mining Industry in the United Kingdom.' The lectures will take place on Feb. 19th, 24th, and 26th, and on March 3rd and 5th, at 5 o'clock in the afternoon. Dr. Shufflebotham will pay special attention to the conditions under which coal-miners work, to the causation and prevention of accidents and explosions, and he will deal with the questions of poisonous gases in mines, dust, high temperatures, as well as with miners' nystagmus, beat-hand, beat-elbow, and miners' skin diseases. The lectures will be illustrated by lantern slides, and at the lecture on miners' nystagmus on March 3rd there will be a demonstration on living cases.

IN our last issue we gave preliminary details of the fifth annual session of the Clinical Congress of Surgeons of North America which is to be held in London during the week commencing July 27th next; but we may repeat that temporary offices for the Congress have been established in the building of the Royal Society of Medicine, No. 1, Wimpole-street, W., and inquiries may be addressed to the Secretary-General, Dr. Franklin H. Martin. Sir Rickman J. Godlee is chairman of the London Committee of Arrangements, and Mr. H. J. Paterson and Mr. H. S. Pendlebury are the honorary secretaries. It is expected that 1200 to 1500 surgeons from the United States and Canada will be in attendance at the meeting in London.

THE King has approved the appointment of Mr. John Carswell as a Medical Commissioner in Lunacy for Scotland. — The Secretary for Scotland has appointed, under the provisions of the Mental Deficiency and Lunacy (Scotland) Act, 1913, Dr. Kate Fraser and Dr. James P. Sturrock to be Deputy Commissioners of the General Board of Lunacy for Scotland.

THE TRAINING OF MEDICAL OFFICERS OF PRISONS.

(FROM A CORRESPONDENT.)

IN a letter which appeared in the *Westminster Gazette* of Jan. 22nd Surgeon-General G. J. H. Evatt asked a series of questions regarding the mode of appointment, the professional qualifications, and the conditions of service of the medical men who are employed under the Prisons Department of the Home Office. As some portion at all events of the information which he sought is to be found in such readily accessible sources as the introductory pages of the Medical Directory, we shall hardly do Surgeon-General Evatt an injustice in assuming that his questions were to be regarded as being to some extent of a rhetorical character, and intended not so much to secure the satisfaction of his own doubts as to stimulate the curiosity of his readers. This is, of course, a perfectly legitimate way of attaining what is doubtless an entirely laudable end, but some of his questions which imply an attitude of criticism are not likely to receive answers in a lay journal, even though one which is distinguished by its broad and fair views be in question. If his letter has the effect of provoking intelligent discussion of the many important problems that arise in connexion with the medical aspects of prison work, so much the better.

Surgeon-General Evatt's suggestions—for, in spite of their interrogative form, it is in the light of suggestions that we may regard most of his remarks —were mainly of interest from the conception which they implied of the rôle of medical science in the [illegible] view Surgeon-General Evatt is really perpetuating a peculiarly mischievous tradition. Not that his criticism of the present organisation of the prison service, as still bearing traces of the army system, is without distinct force, but he has missed the point that it was not because it was bad of its kind that the army system had an evil influence on penal administration. It was because, being designed for the special conditions of an army, it was necessarily unsuited for the needs of a prison. If there is one fact definitely established by the failure of penal administration in the past, it is assuredly the futility of applying military methods to the treatment of the criminal; it is not on the barrack but on the lunatic asylum that the prison should be modeled, and it is idle to look for any real progress in prison reform except through the permeation of the prison system by something approaching the psychiatric spirit. This principle, almost a truism of modern criminology, is so little appreciated that we find a medical man of Surgeon-General Evatt's position considering a knowledge of mental diseases as less important for a prison doctor than the possession of a sanitary diploma. The connexion of crime with mental disability is not in any way recognised by suggesting that medical officers of prisons should receive lectures from specialists on mental disorders at lunatic asylums. It would be of very mischievous effect if this utterly inadequate standard of psychiatric training should be put before the public as satisfying the requirements of prison work, and it is therefore desirable that medical opinion should be at once dissociated from so reactionary a view. The point is of considerable importance, for it touches principles that are essential in the modern conception of the treatment of the criminal. This has, in fact, been so well recognised that the last Departmental Committee on Prisons, which reported in 1897, strongly recommended that practical experience in the treatment of insanity, such experience, that is to say, as can only be acquired by actual asylum work, ought to be an indispensable condition of appointment to the medical branch of the prison service.

This sound principle has not, unfortunately, received statutory sanction in the Prison Act of 1898, though a recommendation to this effect is allowed to remain as a pious exhortation, on the understanding that effect would, as far as possible, be given to it in practice. It is to be regretted that the position was not clearly defined in the Act by making adequate psychiatric training a statutory qualification for the prison service. This would have done much to promote that closer association of prison and asylum work which is so essential to the growth of a scientific criminology, and it would also have helped to make clear to the minds of prison reformers the goal to which their efforts can be most usefully directed. These are matters in which the public mind certainly needs enlightenment, and any such discussion of them as may definitely establish the paramount importance of psychiatry in the treatment of the criminal would be welcomed by the medical profession.

THE HEALTH OF THE ARMY IN 1912.

FROM the report on the health of the British army that has just been issued,[1] it will be seen that while the proportions of admission to hospital and of invalids finally discharged are very slightly in excess of those in the previous year, the death ratio and ratio of men constantly sick in hospital are even lower than in 1911; while in every respect the improvement in comparison with the average health statistics of preceding periods is most marked. The following are ratios per 1000:—

	Admissions.	Constantly sick.	Deaths.	Invalids.
1889–98 ...	... 997·3 ...	59·85 ...	9·03 ...	15 36
1907–11 ...	... 498·6 ...	28·75 ...	4·17 ...	9·57
1911 ...	... 421·1 ...	24·28 ...	3·47 ...	8·09
1912 ...	... 426·3 ...	23·72 ...	3·26 ...	8·25

If the number of men suffering from trivial ailments and disabilities under treatment in barracks be added to those sick in hospital, the total ratio of sickness only amounts to 31·59 per 1000, little more than half the constant inefficiency before the South African war.

The active strength of the army, amounting to 213,678 warrant- and non-commissioned officers and men, may be divided into three groups: about one-half of the force (107,582) are stationed in the United Kingdom; the remainder are either serving in India (71,001) or in the various colonies and dependencies (35,095). As compared with the year 1911, there is a slight increase in the admission ratio for India (547·9 in place of 524·7 per 1000) and for the entire army (426·3, compared with 421·1); and in the invaliding ratio for the colonies (8·95, compared with 6·02); under all other headings the ratios are practically the same or slightly lower.

Recruiting.

The statistics for recruits are now prepared for the "recruiting year" from Oct. 1st to Sept. 30th, instead of for the calendar year as formerly. For the period 1911–12 the number of recruits brought forward for medical inspection, 47,008, was more than a thousand less than in the year 1911, and far below the preceding decennial average of 62,140. This serious deficiency is attributed partly to emigration and partly to improved conditions of trade. The proportion rejected on medical examination was 237 per 1000, a reduction on the figure for the previous year (257) and on the decennial average (321). This improvement, however, is not attributed to any general improvement in physique in the classes from which the recruits are drawn, but to alterations in detail effected in the primary examination by the recruiters, and in the coördination and standardising of the medical examination, and to improved methods of physical training, also to a relaxation of the requirements in certain particulars, such as chest measurement and the condition of the teeth. The rejections for chest measurement were only 29 per 1000, compared with the decennial average of 49; for dental deficiency the rejections were 22, compared with 56 (due to lessened stringency of requirements). Heart disease (37 per 1000) was a more frequent cause of rejection than in the previous decennium (27 per 1000). It is considered that the rejection ratio is too high, many cases being for comparatively harmless functional diseases, such as tachycardia from cigarette smoking. Defective vision (21) was not so frequent a cause of rejection as in the preceding decennium (29 per 1000). In regard to the maintenance of a good standard of recruit (excluding those under 18) the average age was 19·6 years, average height 66·2 inches, minimum and maximum chest measurements (average) 33·3 and 35·6 inches respectively, range of expansion 2 6 inches, and weight 127·8 lb. All these figures are almost precisely equal to those of the preceding decennium, and may be considered satisfactory. The standard of vision was relaxed in 1912. With normal vision in the better eye, not more than 6/60 is required in the other, the recruit being accepted for certain corps only if the right eye be the one defective. The present system of physical training continues to give satisfactory results. A series of observations at Aldershot showed that with each week's training there was a progressive tendency to more rapid return to normal of the pulse-rate after "a full obstacle course."

Sanitation.

A short section of the report deals with the progress of sanitary administration in general throughout the army. Systematic instruction in the principles and practice of this important subject is now given to the cadets at Sandhurst and Woolwich, and practical demonstrations in the field, as well as lectures, are given at the School of Army Sanitation at Aldershot, where 900 officers and men of various branches passed through the courses during the year. It is noted with satisfaction that improvement has taken place in the sanitary administration of barracks and camps throughout the country, and that commanding officers are more and more alive to their responsibility in this regard, and cordially coöperate with medical officers in carrying out recommendations. The health of the troops has been good both in barracks and camp, and this fitness is maintained by a monthly inspection of every soldier, any man in a doubtful state of health receiving special attention. As regards experimental work at the Royal Army Medical College and School of Army Sanitation, the chief results have been that it has been found possible to clarify water thoroughly before passing it through the candles of the regulation filters; as the result of practical tests on experimental marches a new emergency ration has been devised, and bacon and cheese have been added to the ordinary field service ration; the purification of the water of swimming baths has been investigated; and observations have been made and experiments carried out on the heating of wards and barrack rooms, on the efficacy of gaseous disinfectants, and on the preservation of army biscuits from attacks by the larvæ of moths.

Invaliding.

The ratio for invaliding (final discharge from the service) was 8·25 per 1000, being 0·16 per 1000 higher than in the previous year, the increase occurring in men serving abroad. Diseases of the nervous system (1·61) form the highest proportion, being, however, less frequent than in almost any previous year. Circulatory diseases (1·27) are fractionally higher than in 1911, but less than in any year preceding. Tuberculous affections (1·18) were practically the same as in 1911, and syphilis (0·11) led to the invaliding of only 25 men, the ratio being much lower than any previously recorded.

Health of the Troops in the United Kingdom.

The improvement that has been manifested in the health of the home forces during recent years is shown concisely in the following table (the figures are ratios per 1000):—

	Admissions.	Constantly sick.	Deaths.	Invalids.
1889–98 ...	712·5 ...	41·14 ...	4·32 ...	16·98
1907–11 ...	387·0 ...	22·15 ...	2·69 ...	11·59
1911 ...	346·3 ...	20·08 ...	2·47 ...	9·78
1912 ...	346 4 ...	19·50 ...	2·34 ...	9·37

There is but little variation from the figures for 1911, but there is a decrease in all items compared with the preceding quinquennium. The figures for admission to hospital and constant inefficiency from sickness are less than half, and those for mortality and invaliding not much more than half, the ratios for the period before the South African war.

The admissions were highest in the London District, 629·2, and lowest in the Western Command, 241·8 per 1000. The constant inefficiency from sickness was also highest in London, 35·67; the lowest ratio being 11·85, also in the Western Command. As regards the different arms of the service, the Household Cavalry, as always, show the highest admission rate (707·3); and the Foot Guards the highest number constantly sick (34·54); the Infantry of the Line have had only 359 4 and 20·77 respectively. The most fatal disesses amongst soldiers at home were pneumonia (causing 32 deaths), pulmonary tuberculosis (18 deaths), and appendicitis (12 deaths). The diseases causing most sickness were the venereal group, which together gave a constantly sick ratio of 5·51, out of the total 19·50 per 1000; the chief causes of invaliding out of the service were tuberculosis (1·38 per 1000, of which 1·19 was pulmonary), nervous diseases (1·11), and valvular heart disease (1·12).

India.

The average strength of the European force in India during 1912 was 71,001 warrant and non-commissioned officers and men. The following table shows the great improvement in health that has taken place in recent years (in ratios per 1000):—

---

[1] Report on the Health of the Army for 1912. H.M. Stationery Office, 1913. Price 1s. 6d.

	Admissions.	Constantly sick.	Deaths.	Invalids.
1889–98 ...	1464·7 ...	89 61 ...	16·43 ...	14·78
1907–11 ...	679·7 ...	38·49 ...	6·77 ...	7·17
1911 ...	524·7 ...	28·81 ...	4·89 ...	6·20
1912 ...	547·9 ...	28·86 ...	4·82 ...	5·94

As compared with 1911 there is a slight increase in the admission ratio, the other figures being practically the same as for that year. Compared with the preceding quinquennium, and still more if the statistics before the South African war be examined, it is seen that the constantly sick and mortality ratios are less than one-third, the admission ratio not much more than one-third, and the invaliding considerably less than one-half the average of the former period.

The greatest number of admissions to hospital have been due to malaria (82·4 per 1000), almost exactly half the ratio for the preceding quinquennium (163·8). Sandfly fever was, however, extremely prevalent, the admissions amounting to 30·5 per 1000, compared with the quinquennial average of 5·4; but pyrexia of uncertain origin caused only 21·2, compared with 47 per 1000 in the former period. No doubt in previous years the diagnosis between these affections was frequently uncertain; for all three together the ratios came to 134·1 in 1912 and to 216·2 in 1907–11. Venereal diseases caused 55·5 per 1000 admissions, compared with 67·8 in the preceding period, and to these affections was also due the greatest inefficiency, their constantly sick ratio being 7·06. The most fatal diseases were enteric fever (0·37), inflammation of the liver (0·34), and pneumonia (0·28 death per 1000).

For enteric fever the number of admissions, 118, was the lowest on record, being only 1·7 per 1000 of strength; if the admissions for paratyphoid A and B be added the ratio is still only 2·6. The enteric admission ratio for 1907–11 was 8·5, and for 1895–1904 it was 22·3; these figures bear the most eloquent testimony to the immense improvement in sanitary conditions that has taken place in recent years and need no comment. The death ratio in 1912 was 0·37 per 1000 (or, including paratyphoid A and B, 0·39); for 1907–11 the ratio was 1·59; for 1895 to 1904 it was 5·62. The largest number of cases in any one division occurred at Secunderabad, where there were 26 (with 5 deaths); in the Poona division there were 19 cases (no deaths); in the Lucknow division 15 cases with 6 deaths. Anti-enteric inoculation is carried on vigorously: 90 per cent. of the European troops have been inoculated. The enteric admissions among these men were in a ratio of 1·20, and the deaths in a ratio of 0·15 per 1000; for the non-inoculated these ratios were 6·69 and 2·69 respectively; the relative case-mortality ratios were 12·8 and 40. For paratyphoid fever inoculation does not seem to have afforded much protection; 64 cases were admitted during the year, only one of which had not been inoculated. The enteric fever depôts at Naini Tal (for Northern India) and Wellington (for the South) have been of the greatest service. Uncertain and possibly dangerous cases are sent to these depôts, where careful and prolonged examinations of excreta are carried out, as well as examinations of cultures forwarded from all parts of India. Important work has also been done in regard to the viability of paratyphoid A bacillus in dejecta buried in earth; in the cold weather such fæces remained infectious for long periods, but in the warmer months they became innocuous within ten days, owing to the multiplication of saprophytic bacteria; the bacillus did not survive in infected flies more than 24 hours.

The year 1912 was not a bad year for fever in India, and for the British troops the malarial admissions were only 82·4 per 1000; for sand-fly fever the admission ratio was 30·5; the admissions for [illegible] accuracy of dia, [illegible] for the reductic [illegible] the use of mosquito nets by troops is general there is unlikely to be any great reduction in malaria prevalence. The Government of India have definitely decided to incur no expense in providing nets for soldiers other than in a few selected places; the provision, therefore, of these protectors for the men depends entirely upon regimental initiative." It is extremely regrettable that such an obscurantist and short-sighted attitude should be adopted by the Indian Government. In former years very large sums have been expended on improvement of water-supplies and sanitary amelioration generally; the result in the improved health of the troops (and their consequent efficiency) is manifest. At the present time one of the most certain means of prevention for malarial fever is quite well known and of easy application—viz., mosquito netting. In stations that are notably malarial we hold it to be the duty of the Government to provide protection for its servants, and to insist that this protection be made use of. Discipline can effect the latter, money is required for the former; it should not be left to the private soldier in a feverish station to pay for his own protection from malarial mosquitoes.

Of small-pox there were 17 cases, with 3 deaths, a much higher incidence than in any recent year; 2 of the fatal cases had been vaccinated, the third had unsatisfactory marks; each of the non-fatal cases had been vaccinated in infancy, and in each revaccination on entering the army had failed. There were an unusually large number of admissions for dengue (364 = 5·1 per 1000), mostly in Calcutta and Madras, where the disease is prevalent among the native population. There appears to be some reason to suspect infection by sand-fly bites. No cases of beri-beri are returned, but 60 cases of multiple neuritis occurred, mostly in Calcutta and other Bengal stations. Two deaths resulted from cardiac failure. For venereal affections the admission ratio, 55·5 per 1000, shows a slight increase on the ratio for 1911 (53·1), although the reduction on the quinquennial figure (67 8) is decided. For syphilis the admissions have diminished, but for gonorrhœa and soft chancre there has been a slight increase over the previous year. These diseases are most prevalent in Burma (84), Secunderabad (74·7), and Lucknow (72·7); least in Rawal Pindi (34·2) and Quetta (39·1 admissions per 1000). The modern treatment by salvarsan is carried out in conjunction with after-treatment by mercury and iodides. There have been no untoward results.

Other Stations Abroad.

In Egypt there was maintained a force averaging 5508 men; the admission (507·4), constantly sick (34·22), and invaliding (10·71) ratios were higher than in 1911, but (except for the last named) lower than in the preceding quinquennium. For enteric fever there were 52 admissions (9·4 per 1000), more than in any year since 1902; 33 cases occurred at Abbassia in April and May, traced to an active carrier, who had had the disease in 1911, had been given a clean bill of health in June (the dejecta having been free from infective organisms since April), but who was found in 1912 to be again excreting B typhosus abundantly. He was not a cook, but occasionally helped in the preparation of teas for his troop. Malaria occurred at Khartoum, after heavy rainfall; and at Alexandria, among men infected in Cyprus. Tonsillitis broke out in an acute form in Cairo and in Khartoum, ascribed to infected dust at the latter station, and in Cairo to food infected by dust. Bilharzia infection caused 39 admissions in Cairo, attributed to a floating bath in the Nile; this has now been done away with.

In Gibraltar and Malta the health statistics were satisfactory; 3 cases of Mediterranean fever occurred in Malta, 2 being definitely traced to goats' milk.

In the South African Command the average strength of troops was 10,488, with an admission ratio of 343·1, average constantly sick 23·60, and deaths 3·53 per 1000. The constantly sick ratio is somewhat above the quinquennial average (21·78); the other ratios are lower. The general health of the troops is described as having been excellent. For enteric fever there were 25 admissions and 4 deaths; 11 of the cases occurred at Pretoria and 9 at Tempe. Food contamination by flies and the consumption of fruit and vegetables handled by natives are thought to have been likely causes. No cases occurred at Tempe after the wet system of conservancy, with cresol, had been introduced. It certainly causes surprise to learn that this method had not been brought into universal use in such a climate as South Africa some years ago. In North China there were a considerable number of admissions for malaria at Tientsin and Peking, all of benign tertian infection; the parasite was demonstrated microscopically in every case. The disease must have had a local origin (as the men had in most cases not

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Berkshire.—The most important recent feature of public health administration by county councils has in most cases been their sanatorium and dispensary provision and the general county arrangements for prevention of tuberculosis, and these questions naturally bulk largely in the series of annual reports of English county medical officers of health which have appeared during the last few months. It is, however, regrettable that, in consequence of the official scheme of reporting, the accounts now available do not, as a rule, include the developments which took place last year, but relate only to the action taken in 1912, which (so fast have administrative schemes developed) is often very little guide to the present position. County medical officers are, of course, handicapped in reporting earlier on matters which are under their direct charge by the official requirement that they are to include in their annual reports a digest of all annual and special reports of the medical officers of health of the various sanitary districts in their counties, and are to review a number of questions which have fallen under the district rather than the county jurisdiction during the year reported on. It has been suggested that reviews of this kind might be carried over to the following year's report without loss of usefulness. There can be no doubt, however, that they can be made very valuable, and Dr. Gerard C. Taylor's report on the public health of Berkshire is a good example of their utility. We would specially commend the introductory tables, which give names, addresses, telephone numbers, and the like of the medical officer of health of each sanitary district, corresponding particulars of the sanitary inspectors, census figures for each district and parish, their death-rates, crude, corrected, and various other details which, though they may seem small individually, add greatly to the practical value of the volume to all concerned with public health work in the county. We think, too, that there is much to be said in favour of the plan which Dr. Taylor follows when he prefaces his account of the position of the various districts in such matters as hospitals, water-supply, and housing, by concise statements of the powers and duties of the local authorities in regard to them. In the section relating to infectious disease Dr. Taylor mentions the discovery, in consequence of the appearance of diphtheria at Cookham Rise school, of two children who were carriers of the diphtheria bacillus, although showing no symptoms of diphtheria. One of these carriers received persistent treatment for some three months, at the end of which she developed definite clinical symptoms of diphtheria. The case is, of course, not very singular, but it is so frequently assumed that the diphtheria carrier is immune to attack that it deserves notice.

County of Staffordshire.—Much of the time occupied during 1912 in elaborating a county scheme for dealing with tuberculosis in Staffordshire was devoted to the discussion of a promising proposal for amalgamation of this work under a single administrative authority, which would act for the whole of the county and for numerous county boroughs as well. The amalgamation has only been partially effected; it includes the county and the two county boroughs of Wolverhampton and Dudley, but other outside authorities have preferred each to make its own arrangements. It is easy to understand that local preference would generally be in the direction of independence. It remains to be proved by experience that the smaller county boroughs can in this way do as well for their tuberculous cases, and it will be instructive in future to compare their position with that of Dudley and Wolverhampton. In dealing with enteric fever in Staffordshire Dr. George Reid lays stress on the steady and uninterrupted decline which is taking place in the mortality from this disease both in urban and rural areas. In the former enteric fever death-rates per 1000, which in the five-yearly periods 1889–93, 1894–98, 1899–1903, and 1904–08 were respectively 0·15, 0·2, 0·16, and 0·09, have diminished to 0·04 in 1912, while in the latter the corresponding figures are 0·12, 0·08, 0·09, and 0·03, which is also the figure for 1912. The gradual abolition of privies and the substitution of water-closets, as well as the extension of public water-supplies, must be given the greatest prominence among the reasons of this gratifying diminution. Improvements are by degrees being effected in the quality of water in the rivers and streams of Staffordshire by the efforts which are made to secure satisfactory means of sewage disposal. Manufacturers' effluents, of course, often contribute largely to pollution of rivers, and it is desirable that local authorities, which usually obtain substantial sums in the way of rates from the factories in their districts, should wherever possible take these trade wastes into the public sewers so that they may be purified, with other sewage, at the outfall works. Milk factories may be great offenders in the matter of trade wastes, and at Uttoxeter considerable difficulty seems to have arisen through the district council taking the shortsighted policy of refusing to admit the effluent into the sewers, notwithstanding the reiterated advice of the county council, the Local Government Board, and the Royal Commission on Sewage Disposal. Needless pollution of the river consequently goes on, the public health committee of the county feeling that it would be inequitable to prosecute the manufacturers, while the county authorities are apparently unable to coerce the district council. In this county systematic inspection of the sanitary condition of urban districts by the county medical officer of health or his assistants has been in progress for some time, and seven of these were inspected in 1912. Dr. Reid anticipates that good will result from the representations which have been made to the district councils as a result of these inspections. The notification of ophthalmia neonatorum, if we remember right, came into practice in Staffordshire largely on Dr. Reid's initiative. At present this affection is notifiable in rather more than half the area of the county, including about three-fourths of its population, but some districts seem to have been content to adopt the notification—a useless proceeding by itself—without making suitable arrangements for the immediate treatment of the new-born infants found to be affected. The county scheme for providing gratuitous bacteriological examinations in suspected cases of diphtheria, enteric fever, and tuberculosis is said to be successful, when judged by the increasing numbers of specimens submitted. The cost to the county per specimen is 5*s.* in the case of diphtheria (2*s.* 6*d.* in the case of diphtheria contacts), 3*s.* for tuberculosis, and 5*s.* for enteric fever. In reporting on the administration of the Midwives Act Dr. Reid draws attention to the fact that midwives now send for medical help to a much larger extent than formerly. In the absence of a statement of the number of births attended by midwives during the year no percentage can be given, but in 1912 the total number of requisitions for medical help was 893, the total births, whether attended by midwives or not, being 18,332.

County of Nottinghamshire.—In this county 21 cases of puerperal fever, with 8 deaths, were reported in 1912, and Dr. H. Handford, commenting on the smallness of the former figure, refers to the unwillingness of many members of the medical profession to notify cases of puerperal fever. Attention has often been drawn to the unreliability of puerperal fever notification, but it is not, we think, generally supposed that the occurrence of puerperal fever in the practice of midwives goes unreported by medical men where they meet with it. Dr. Handford, however, states that this reluctance to notify constitutes one of the greatest hindrances which local supervising authorities have to overcome in carrying out the Midwives Act and in supervising the practice of midwives. While drawing attention to the pressing need for new milk legislation, and the harm done by its continued postponement, Dr. Handford is able to show that even under existing conditions a considerable advance has been made by some of the more progressive sanitary authorities in Nottinghamshire towards reducing the risk of tuberculous milk. In the urban district of Newark, for example, there are dairy and veterinary inspectors who systematically visit cowsheds and take measures to eliminate diseased cattle; the work of locally appointed veterinary surgeons is referred to in the case of several other districts, including Worksop, where 812 animals were examined for tuberculosis; Sutton-in-Ashfield, where every cow in milk was subjected to veterinary inspection during the year; and Kirkby-in-Ashfield, where the appointment of a veterinary inspector was justified by the discovery of 15 cows with tuberculosis of the udder out of 242 cows inspected. The opportunities for useful work of this kind should be increased by the Tuberculosis of Animals Order of last year, and it is to be hoped that it will be continued. The report brings out forcibly the importance of not confining public scavenging and similar work to urban centres. The organised removal of refuse is one of the principal needs of many villages and comparatively small communities. Another matter which should receive attention in rural districts on the outskirts of manufacturing centres is the prevention of smoke nuisance. The proper consumption of smoke results not only in greater amenities and better health to the public, but also usually in financial benefit to the manufacturer, and local authorities should not hesitate to press their powers in the matter, even when the offending factory is more or less "out in the country."

REPORTS OF SCHOOL MEDICAL OFFICERS.

Hampshire County Council.—Dr. R. A. Lyster's report includes the record of a special investigation made to determine the frequency of pulmonary tuberculosis. 230 children taken at haphazard were very carefully and systematically examined on a pre-arranged plan by the inspectors and their results give a percentage of pulmonary tuberculosis of 3·5. This means that in the Hampshire schools there are 1800 cases of this disease. A full discussion of the part of the school doctor in the campaign against tuberculosis follows. The investigation points to the malnutrition of many children and the inspectors say, "Ignorance and intemperance, bad management and short-sighted extravagance are, it is true, on every hand, but it must be admitted that most of the poverty and malnutrition is due to involuntary and not voluntary causation. We are unanimously and strongly of opinion that any measure which tends to improve the nutrition of our school children must be a potent—probably the most potent—weapon in the fight against tuberculosis."

Nottinghamshire County Council.—Steady progress is recorded by Dr. H. Handford The percentage of parents attending examinations has risen steadily in the years 1909 to 1912; the figures are 49·6, 50·0, 51·2, and 54·5. The percentage of cases treated for defects notified at inspection has risen also, the corresponding figures being 34·6, 45·9, 41·3, and 63·1. Only the worst dental cases are notified and a vision clinic swells the percentage for 1911.

Gloucestershire County Council.—An important change in administration is recorded by Dr. J. M. Martin, the work of medical inspection having been placed largely in the hands of the medical officers of health of four large combined sanitary districts covering nearly two-thirds of the county. The proportion of untreated defects has fallen from 35·4 to 19·9 in three years. But the percentage found to be tuberculous has gone up from 0 46 to 1·34. This was due to an increase in cases of pulmonary disease discovered by Dr. Madeleine Baker, who had made a special study of the disease and left to become a tuberculosis officer in Wales. Dr. Baker found 64 cases among 2619 children examined by her, whereas two other medical inspectors found only 15 cases amongst 4884 children.

West Riding of Yorkshire.—Dr. J. R. Kaye's report is a well-arranged document; the index is useful, and the list of the medical staff with the number of departments and children under their control gives information which is frequently left out and which might be copied (and amplified) by other authorities. Care committees exist in 83 districts, and valuable work has been done.

Bilston Urban District Council.—Dr. T. Ridley Bailey notes that among 413 children examined before leaving school 30 per cent. had some defect, as against 48·4 per cent. the previous year. The decline is partly attributed to the examination (and presumably treatment) of "special cases" at an earlier period of school career. The report ends by stating that "slums ...... must be abolished," and further, "that destitution and extreme poverty shall be, as they should be, regarded as a disgrace to humanity and civilisation and no longer allowed to exist, whatever may be the cost—in money and endeavour—required for their final eradication." To this conclusion many school medical inspectors will be driven, and we welcome its explicit statement.

Northamptonshire County Council.—Various experiments are recorded of interest, and among them the provision of "exercise corridors open to the air on one side" in four schools and of open-air class-rooms protected from the weather by a light roof in several places. Provision for school gardens is made in all new schools except those for infants only. A comparison of cleanliness of teeth shows urban cleaner than rural children and girls than boys. A reduction in cases of ear disease (1911, 62 cases; 1912, 40 cases) is concurrent with reduction in tonsillar enlargement. Dr. J. H. Mason gives full and good tables of statistics from which interesting comparisons of urban and rural children may be made.

Staffordshire County Council.—Dr. George Reid presents the report of the senior school medical inspector (Mr John Priestley), to which are added some valuable special reports on heart disease, ringworm, and temperatures of school children. The four assistant school inspectors are all women, and each to a large extent is autonomous in her area. "In short, each inspector is made to feel that the children of her schools are her own medical 'flock.'" A very curious numerical relationship is noticed in considering the history of children who have had infectious diseases The figures are the same (with the exception of mumps due to a wrong diagnosis by teachers) for six years, and those for 1910 may serve as an example. The children having had measles are taken as 1000, when the other figures are whooping-cough 452, chicken-pox 252, scarlet fever 173, mumps 83, and diphtheria 44. The geometrical progression is almost uncanny. Another interesting point raised is as to whether some skins "repel lice." It would appear to be the case. The report on heart cases deals with 34,244 children inspected in 1908–09, among whom were 1767 children, or 5·16 per cent., showing some cardiac disturbance. There were 1467 functional, 30 congenital, and 270 organic valvular disease. Dr. Lila S. Greig analyses the cases admirably. The [illegible] port gives two [illegible] les, whooping-cough, diphtheria, and scarlet fever in each week of the year, also a copy of the instructions issued to parents and teachers for dealing with infectious illness. Estimates for the establishment of a school clinic are given.

Cumberland County Council.—Dr. F. H. Morison's report devotes a considerable amount of space to consideration of building and equipment of schools. Some diagrams are given. Of 12,419 children examined, 1·5 per cent. were classed as phthisical, 4 4 per cent. as pretubercular, 2·2 per cent. as weak-chested, and 0 3 per cent. as delicate. The print of this report is too small.

Rutland County Council.—Rupture was found to be actually present or foreshadowed by the existence of large external abdominal rings in 7·2 per cent. of the boys of the entrant and leaver group. Two of these were umbilical hernia, the remainder inguinal. A small dental treatment scheme under the education committee is in operation at Oakham, being privately paid for.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8961 births and 5750 deaths were registered during the week ended Saturday, Feb. 7th. The annual rate of mortality in these towns, which had been 17·0, 17·5, and 18 4 per 1000 in the three preceding weeks, declined to 16 5 per 1000 in the week under notice. [illegible] the current quarter the mean [illegible] towns averaged 17·7, against a [illegible] 1000 in London. Among the [illegible] th-rate last week ranged from [illegible] rd, 8·1 in Walthamstow, 8·5 in [illegible] nd in [illegible] 9 in [illegible] n the [illegible] sles, [illegible] t one [illegible] these [illegible] effield and in Swansea, 1·9 in Burnley and in Barnsley, 2·0 in Dudley, 2·4 in Rotherham, 2·6 in Gateshead, and 3·2 in West Hartlepool. The deaths referred to diphtheria, which had been 70, 68 and 85 in the three preceding weeks, declined to 70 last week; of this number 19 occurred in London, 8 in Birmingham, 4 in Manchester, 3 in Northampton, 3 in Sheffield, and 3 in Aberdare. The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 80, 68, and 93 in the three preceding weeks, fell to 66 last week, and included 21 in London, 4 in Liverpool, 3 in Birmingham, 3 in Manchester, and 3 in Rhondda. The deaths attributed to measles, which had been 55, 70, and 79 in the three preceding weeks, declined to 64 last week; the highest annual death-rates from this cause were 1·6 in Middlesbrough, 1·7 in Cardiff, 2·0 in Ipswich, and 5·2 in Burnley. The deaths referred to scarlet fever, which had been 37, 41, and 29 in the three preceding weeks, rose to 38 last week, and included 5 in London, 4 in Birmingham, 4 in Liverpool, 3 each in Manchester, Salford, and Sheffield, and 2 in West Ham. The fatal cases of enteric fever, which had been 21, 17, and 21 in the three preceding weeks, were again 21 last week, of which 8 occurred in London, 3 in Manchester, and 3 in Halifax.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3676, 3567, and 3599 at the end of the three preceding weeks, had declined to 3554 on Saturday last; 379 new cases were admitted during the week, against 388, 375, and 460 in the three preceding weeks. These hospitals also contained on Saturday last 1137 cases of diphtheria, 276 of whooping-cough, 71 of enteric fever, and 65 of measles, but not one of small-pox. The 1441 deaths from all causes in London were 116 fewer than the number in the previous week, and were equal to an annual death-rate of 16·6 per 1000. The deaths referred to diseases of the respiratory system, which had been 400, 421, and 425 in the three preceding weeks, fell to 347 in the week under notice, and were 100 below the number recorded in the corresponding week of last year.

Of the 5750 deaths from all causes in the 97 towns, 190 were attributed to various forms of violence, and 439 were the subject of coroners' inquests. The causes of 51, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 68 other smaller towns. Of the 51 uncertified causes of death last week, 12 were recorded in Birmingham, 7 in Liverpool, 6 in Gateshead, 3 in London, 3 in Bootle, and 2 each in Southend-on-Sea, Blackpool, and South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1207 births and 807 deaths were registered during the week ended Saturday, Feb. 7th. The annual rate of mortality in these towns, which had been 20·4, 20·9, and 20·0 per 1000 in the three preceding weeks, declined to 18·4 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 20·0, against 17·7 per 1000 in the 97 large English towns during the same period. Among the several Scotch towns the annual death-rate last week ranged from 7·6 in Motherwell, 12·3 in Perth, and 14·7 in Greenock, to 23·5 in Kilmarnock, 26·7 in Falkirk, and 31·1 in Hamilton.

The 807 deaths from all causes were 71 fewer than the number in the previous week, and included 68 which were referred to the principal epidemic diseases, against 100 and 91 in the two preceding weeks. Of these 68 deaths, 34 resulted from measles, 15 from diphtheria, 7 from infantile diarrhœal diseases, 6 from scarlet fever, 5 from whooping-cough, and 1 from enteric fever, but not one from small-pox. These 68 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·5, against 1·1 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 29, 51, and 48 in the three preceding weeks, further declined to 34 last week; of this number 18 occurred in Glasgow, 4 in Greenock, 3 in Edinburgh, 3 in Hamilton, 2 in Leith, and 2 in Coatbridge. The deaths referred to diphtheria, which had been 13, 19, and 14 in the three preceding weeks, were 15 last week, of which 9 occurred in Aberdeen and 4 in Glasgow. The fatal cases of diarrhœa and enteritis (under 2 years), which had been 8, 9, and 12 in the three preceding weeks, fell to 7 last week, and included 3 in Glasgow. The deaths attributed to scarlet fever, which had been 8, 15, and 10 in the three preceding weeks, further declined to 6 last week, of which 4 were recorded in Glasgow. The 5 deaths referred to whooping-cough, comprising 4 in Glasgow and 1 in Coatbridge, were slightly below the average in the earlier weeks of the quarter. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 230, 230, and 189 in the three preceding weeks, further fell to 179 in the week under notice; 33 deaths were attributed to different forms of violence, against 26 and 36 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 665 births and 507 deaths were registered during the week ended Saturday, Feb. 7th. The annual rate of mortality in these towns, which had been 21·6, 23·8, and 24·0 per 1000 in the three preceding weeks, declined to 21·9 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 23·3 per 1000; in the 97 large English towns the corresponding rate did not exceed 17·7, while in the 16 Scotch towns it was equal to 20·0 per 1000. The annual death-rate last week was equal to 25·3 in Dublin (against 16·6 in London and 18·3 in Glasgow), 21·4 in Belfast, 21·8 in Cork, 16·5 in Londonderry, 24·4 in Limerick, and 11·4 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 18·5 per 1000.

The 507 deaths from all causes were 48 fewer than the number in the previous week, and included 37 which were referred to the principal epidemic diseases, against 39 and 21 in the two preceding weeks. Of these 37 deaths, 10 resulted from scarlet fever, 8 from measles, 7 from infantile diarrhœal diseases, 6 from whooping-cough, 4 from enteric fever, and 2 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·6 per 1000; in the 97 large English towns the corresponding death-rate did not exceed 1·1, while in the 16 Scotch towns it was 1·5 per 1000. The deaths attributed to scarlet fever, which had been 12, 2, and 5 in the three preceding weeks, further rose to 10 last week, of which 7 occurred in Belfast. The deaths referred to measles, which had been 6, 8, and 3 in the three preceding weeks, rose to 8 last week, and comprised 5 in Dublin and 3 in Armagh. The fatal cases of diarrhœa and enteritis (under 2 years of age), which had been 11, 9, and 6 in the three preceding weeks, were 7 last week, and included 3 in Dublin and 3 in Belfast. Of the 6 deaths attributed to whooping-cough, which were equal to the average in the earlier weeks of the quarter, 2 occurred in Dublin, 2 in Belfast, and 2 in Newtownards. The 4 fatal cases of enteric fever were recorded in Dublin, Belfast, Londonderry, and Sligo respectively, and those of diphtheria in Dublin and Lisburn respectively.

The deaths referred to diseases of the respiratory system, which had been 130, 153, and 157 in the three preceding weeks, fell to 132 in the week under notice. Of the 507 deaths from all causes, 168, or 33 per cent., occurred in public institutions, and 10 resulted from various forms of violence. The causes of 13, or 2·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

THE undermentioned are restored to the establishment:—Supernumerary Lieutenant-Colonel Hugh C. Thurston, C.M.G., vice A. R. Aldridge, retired (dated Jan. 24th, 1914); Supernumerary Lieutenant-Colonel and Brevet Colonel Sir William B. Leishman, vice M. W. Russell, promoted (dated Feb. 1st, 1914); and Supernumerary Captain Malcolm Leckie is restored to the establishment (dated Feb. 11th, 1914).

Captain Archer Irvine-Fortescue is seconded whilst studying the Japanese language (dated Dec. 21st, 1913).

Lieutenant Francis D. Cairns resigns his commission (dated Feb. 7th, 1914).

The undermentioned Lieutenants are confirmed in their rank:—Robert B. Price, William V. Corbett, Frank C. Cowtan, Noel T. Whitehead, and Henry C. D. Rankin.

Surgeon-General H. G. Hathaway, C.B., deputy director of medical services to the Eighth (Lucknow) Division, has taken up duty at Headquarters, Lucknow Cantonment. Brevet-Colonel and Lieutenant-Colonel Sir William B. Leishman has been selected for appointment as member of the Army Medical Advisory Board as Expert in Tropical Medicine, vice Lieutenant-Colonel C. Birt, who has been placed under orders for service abroad.

Lieutenant-Colonel C. J. MacDonald has been selected for the increased rate of pay under Article 358 of the Royal Warrant for Pay and Promotion. Lieutenant-Colonel N. Faichnie has arrived home for duty from Meerut Cantonment. Lieutenant-Colonel A. L. F. Bate has been transferred from the Military Hospital at Preston to the Woolwich District. Lieutenant-Colonel C. W. H. Whitestone has been selected to hold charge of the Military Hospital at Hilsea. Lieutenant-Colonel G. W. Tate has embarked for a tour of

the generosity of an anonymous donor, the electro cardiograph had been installed in the electro therapeutic department. The total number o in-patients admitted was 4087, an increase of 63 as compared with the previous year. While th number of out-patients was almost the same as i 1912, there had been an increase of over 8000 re attendances for the dressing of wounds and mino injuries. With increased work the committee regretted to report a reduction of £107 in the total subscriptions received. In the Hospital Sunday and Saturday Funds contribution there was a drop of nearly £500. Mr. Wade Deacon, the chairman of the committee, seconded the adoption of the report. The Lord Mayor (Mr. H. R. Rathbone) proposed a vote of thanks to Mr. Holford Harrison for his services as treasurer and his acceptance of re-election to that office. Referring to the difficulty of obtaining funds for charitable institutions, the Lord Mayor did not altogether agree with Lord Derby's diagnosis as to the cause of the difficulty—i.e., that it was due to the Insurance Act—but attributed it rather to increased facilities of communication, so that more people were residing outside the city area and became less conscious of the needs of those who resided in the city and of their responsibilities to the city in which their money was made. The charities of Liverpool were to a very large extent supported by a small number of extremely generous people. Votes of thanks to the medical staff having been passed, the Marquis of Salisbury was elected President for the ensuing year.

ribers of the

Wallasey Cottage Hospital was held at that institution on Feb. 8th, Mr. R. W. Preston, J.P., presiding. Mr. E. S. Wilcox, in presenting the forty-eighth annual report, which he described as probably the worst in the history of the hospital, said the burden of debt with which they began the year had considerably increased in spite of the urgent appeals then made at the time of great prosperity in the business world. Experience showed that although the Insurance Act was now in full operation, the need for voluntary hospitals was as great as ever, and an urgent appeal was made for further subscriptions.

Medical Students' Annual Dinner.

The medical students' annual dinner was held at the Exchange Station Hotel on Jan. 31st, Dr. T. B. Grimsdale being in the chair and Mr. R. E. Kelly in the vice-chair. Over 100 of the students and teaching staff were present, and the evening proved a very enjoyable one.

Feb. 9th.

MANCHESTER.

The Finances of the Royal Infirmary.

THE considerable sum of £7000 is still wanted for the new central branch for accidents and out-patients. An appeal was made for £25,000 to enable the new branch to be opened free of debt, but so far only £18,000 have been promised or received. In the Royal Infirmary itself the number of in-patients under treatment during the year, as will be seen from the annual report which has just been published, was 9049, as compared with 8575 in 1912—i.e., an increase of 474. None the less, the infirmary has *not* been able to cope with the demand upon its in-patient accommodation, for on Dec. 31st of last year no fewer than 548 persons were waiting to enter the hospital for the purpose of undergoing operations of a serious character. A new surgical unit of 60 beds is shortly to be opened. This will entail an additional annual expenditure of £3000. In order to enable the ordinary income to meet the ordinary expenditure £9271 is needed.

Hospital Sunday in Manchester.

Hospital Sunday was observed on Feb. 8th, and everywhere throughout the town notices were widely placarded. There is no doubt that the needs of the medical charities have greatly increased, while the financial help from the churches has diminished. Birmingham and Liverpool subscribe twice as much as Manchester on their Hospital Sundays. The amount subscribed in Manchester last year was only £3135, as compared with £6248 in 1874. Last year the expenditure of the hospitals and other medical charities advanced by £10,000, the total number of patients treated being 344,000. The Lord Mayor has made an appeal for £6000 this year. The actual expenditure of the hospitals last year was £148,000, resulting in a deficit of £20,000 on the ordinary income of the hospitals.

Annual Meeting of the Hospital for Skin Diseases.

At the annual meeting of the subscribers to the Manchester Hospital for Skin Diseases on Feb. 6th it was stated that the debt amounts to £1410. A fact of some importance was reported—viz., that apart from private patients the hospital received £970 in voluntary contributions from the poor people who were treated in the hospital, and this was more than was received from the outside public. Complaint was made of the inadequate support received from outside towns which sent in large numbers of patients. Bolton sent during the year 204; Bury, 186; Crewe, 172; Macclesfield, 155; Oldham, 515; and Stockport, 480.

Estate for Sanatorium at Rochdale.

The Rochdale town council has decided to purchase an estate of about 100 acres called the Springfield estate, Marland, for the purpose of a sanatorium for the treatment of tuberculosis. It is situated about one mile from the centre of the town and will cost from £12,000 to £13,000. About 16 acres will be utilised for the present scheme, and the mansion house will be used as an administrative block.

Bequests to Manchester Charities.

Mr. James Ferguson Power, of Eccles, has left £2000 to St. Mary's Hospitals and the Manchester and Salford Lying-in Hospital and Dispensary; £1000 to the Manchester Infirmary, Dispensary, and Lunatic Hospital or Asylum; and £500 to the Manchester and Salford Blind Aid Society.

Altrincham Hospital.

The appeal of the board of management for the completion of the fund for the enlargement and equipment of this hospital, which was made a week ago, has already resulted in the receipt of £1900 towards the £5000 required.

Meeting of the British Association in Manchester in 1915.

Manchester is taking time by the forelock and has begun already to make preparations for the meeting which will begin on Sept. 8th, 1915. At a meeting held on Feb. 3rd in the Town-hall to make arrangements for the reception of the association in the city a local executive committee, representative of every interest in the city, was appointed, and it was also resolved that a local fund should be raised to defray the expenses of the meeting. This will be the fourth visit of the association to Manchester. The first visit was in 1842, the second in 1861, and the third in 1887, when Sir Henry E. Roscoe was president, and which was one of the greatest meetings in the history of the association. The actual number of members reached 3833.

Negligence of Panel Patients.

New medical cards under the National Insurance Act have been issued in Manchester. The negligence of persons entitled to medical benefit under the Act in Manchester is almost incredible. Through the "dead letter" office no fewer than 54,000 medical cards posted by the Manchester Insurance Committee have been returned. Nearly 280,000 medical cards were sent out, so that about one-fifth of the whole issue failed to be delivered owing largely perhaps to change of address. Meanwhile the Manchester Committee has met the difficulty by issuing special circulars to medical practitioners requesting that:

> Until further notice doctors will not refuse medical treatment to an insured person who has not yet received his new medical card, but can produce the old medical ticket or other satisfactory evidence of his eligibility for medical benefit.

Feb. 10th.

contagion, and the same is the case at other hospitals. Moreover, that the disease is not hereditary, he said, is shown by the fact that in America there were lepers among the immigrants of two or three centuries ago, yet in 1888, when an inquiry on this subject was instituted, it was found impossible to find any among their descendants. It would seem that leprosy is contagious only in a completely unhygienic environment, consequently it is necessary to exercise an effective control, but one which in view of the long duration of the disease shall be much less rigorous than that practised uniformly in all the contagious and epidemic diseases. The report considers it would be useless, therefore, to create special establishments for confining lepers in localities where contagion does not occur, and where neither overcrowding nor uncleanliness prevails. Only in the latter case need the lepers be confined, and this measure will have special application to vagabonds and mendicants. It is proposed to refuse entrance to French territory to foreign lepers, and to expel such as are there if they refuse to submit to the French regulations. Lepers incapable of propagating the disease are to be kept under surveillance, however, and forbidden to exercise certain occupations, particularly those concerned with the food-supply, and this surveillance will be extended to those who live with them. Competent medical men will be appointed to check the diagnosis in each case notified to the authorities. They will advise what steps should be taken and control their carrying out. It is held to be necessary to apply the regulations adopted to the colonies and French protectorates, where the problem has a greater importance than in the metropolis. In the discussion that ensued Professor Gaucher opposed these conclusions, holding them insufficient, and delivered a sharp attack on the general attitude of the authorities and M. Mirman. He divided lepers into three classes, each of which requires a different prophylactic organisation: 1. The indigenous lepers, of which a small group has existed for a long time on the Italian frontier of Provence, in Auvergne, and in Brittany. These cases are known to the inhabitants and are practically isolated, so that they spread no contagion. 2. French lepers returning from the Far East, where they have contracted a much more serious form of leprosy, with contagious ulceration. These should be confined in special hospitals and surrounded by rigorous prophylactic measures. 3. Finally, the foreign lepers, whose entry into France should be interdicted, and those already there should have their choice of confinement or leaving the country. In this respect no surveillance exists, and it must be established. He instanced two cases of lepers recently come to Paris. The isolation of colonial and foreign lepers could be accomplished on some island off the seashore, as has been done in other countries. As to the indigenous lepers, it would suffice to take a census of them and subject them to local surveillance. The isolation at home, of which the Bill brought forward by M. Netter speaks, Professor Gaucher considered to be impracticable. If the leper appeared to be but slightly affected the surveillance would soon relax until it ceased; if he showed ulcerations and required medical care the danger would be just as great for his *entourage*, and complete isolation in hospital would be preferable. After a close vote, which supported the first two of M. Netter's conclusions, the Academy finally referred the entire report for re-examination by the Special Commission.

The Nobel Prize for 1914.

The Academy of Sciences and the Caroline Institute of Stockholm, in whose hands lies the awarding of the Nobel prize, have begun to draw up the lists of candidates for the prize of 1914. The faculties and societies of France that have been consulted as to the French choice have unaminously nominated Professor Bouchard.

Kala-azar at Marseilles.

A child in a Marseilles hospital has been found to be suffering from kala-azar, or leishmaniasis. At the suggestion of Dr. Nicolle, director of the Institut Pasteur at Tunis, Dr. Pringault examined 50 cadavers of dogs at the home for stray dogs at Marseilles, and discovered signs of leishmaniasis in the bone marrow of one of them. The disease, therefore, is existent there, though it has not hitherto been noted. In point of fact, kala-azar is to be found in all the large towns of the Mediterranean, and even at Rome and Turin. The disease attacks only infants from 6 months to 3 years of age, and is nearly always fatal. The transmission of the parasite by dog fleas having been well established, the Société de Pathologie Exotique has called on the Government to take measures to prevent the ingress of dogs from countries where kala-azar is endemic. An inquiry held at Marseilles seems to show that the case observed by M. Pringault is an isolated one, for the other veterinary surgeons of Marseilles have never observed this disease before. The exaggerated statements of the lay press, however, which confounded kala-azar with Indian plague, created quite a panic for many days.

Feb. 9th.

BUDAPEST.

The Sick Clubs and the Medical Profession.

Since the coming into force of the new Workmen's Insurance and Compensation Act the membership of sick clubs in industrial centres and in cities and towns in general has increased immensely with a proportionate falling off in the number of paying patients belonging to the so-called middle classes. In towns containing only a moderate number of industrial undertakings the members of sick clubs are from 26 to 30 per cent. of the inhabitants, while in those which depend mainly on factories, workshops, and similar industrial establishments this proportion rises to 45 or 50 per cent. It is therefore easy to understand that the medical profession looks unfavourably on associations which aim at supplying well-to-do persons with medical aid at low rates. An incident of this kind has occurred at Nagyvarad, where the Baron Hirsch Society, so called after the well-known philanthropist, now deceased, requested the local branch of the Hungarian Medical Association to allow members of the association to occupy two positions with annual salaries of 2000 kronen each (£80), the number of members belonging to the society in question being only 140. The branch association refused the society's request, and the members of the branch have unanimously resolved to decline attending patients connected with the society. The motive for this is not insufficiency of the remuneration offered, because 2000 kronen per annum are fair remuneration for attendance on 70 families, but the association is opposed to any society or combination formed for the purpose of extorting cheaper medical aid from a profession which is so crippled by the Insurance Act. The Hirsch Society has now been advertising for more than six weeks, inviting applications from medical men willing to fill the positions in question, but to the credit of the medical profession it has not yet found a single candidate in the whole country.

Hæmorrhagic Small-pox in Servia.

The Minister of Public Health recently issued an official report announcing that our country is entirely free from cholera, and now a new epidemic is threatening us from Servia, where in the second half of January there was an outbreak of hæmorrhagic small-pox with about 100 cases and 30 deaths up to the present time. The Servian Minister of Internal Affairs has ordered compulsory vaccination. The disease has now spread into Hungary where the first three cases of hæmorrhagic small-pox occurred on Jan. 30th. The Hungarian Minister of Public Health has declared that if further cases occur in any other part of Hungary, he will order compulsory vaccination of all persons living in the infected area.

Conflict between the Insurance Companies and the Hungarian Medical Congress.

At the annual Congress of the Hungarian Medical Association held last September the subject of the fees for making medical examinations for life insurance companies was considered, and it was resolved that when the sums insured were under 5000 kronen the fee should remain at 10 kronen, but that for sums of 5000 kronen and upwards a fee of 20 kronen (16*s.* 8*d.*) shall be charged. Although the medical profession has not raised these fees since the year 1888, and although the present increase is moderate, the elected committee of the insurance companies have declared that they will not consent to the proposed increase, but will rather dispense with medical examinations when the sum insured is under 5000 kronen (£200), and thereby deprive the profession of a considerable income, because in Hungary insurances for even 1000 kronen can be effected, and the fee even in such cases was 10 kronen. If the insurance companies dispensed with these examinations, then they will have to pay the fee of 20 kronen asked when the sum insured amounts to 5000 kronen and upwards. The association cannot modify the resolution of the Congress, which will accordingly be binding on the members, although several branches of the association are in favour of the insurance companies, which quite recently proposed a compromise—namely, that they shall pay 15 kronen for insurances between 5000 and 10,000 kronen. With this modification our fees would be equal to those paid by the insurance companies in Austria and Croatia. The association has sent circulars to all its members informing them that to make insurance examinations for fees lower than have been decided by the association would result in the other members of the association breaking off professional relations with them.

The New Hungarian Universities.

The foundation-stones of two new universities will be laid this year, one in Pozsony (Pressburg), about 40 miles from Vienna, and the other in Debreczen, the most considerable town in the midst of the great Hungarian plain. The universities will have four faculties—namely, theology, law, philosophy, and medicine. The three former will commence work at the end of the present year, but the medical faculty will be in abeyance for the next two or three years because the large university hospitals which are in course of erection will require several years for their completion. There will be difficulty in deciding where the necessary professors are to be got. In Hungary it has been the custom for many decades that people desiring to have the best medical advice go to the capital. This, of course, is extremely profitable for the university professors, their annual incomes varying from 100,000 to 400,000 kronen (£4000 to £16,000). Of course, a Budapest professor cannot be expected to exchange his chair in the capital of the country for a chair in a provincial university, where even his salary would be less. In the provinces, though there are excellent practitioners in great number, there are few who could fill the positions in the universities. For these reasons the Minister of Public Instruction has advised the directors of the various clinics to employ henceforth twice as many demonstrators and other assistants as before in order to have a staff from which the fittest might be selected to fill the chairs of the new universities.

Responsibility of a Medical Man for the alleged Death of a Patient from Poisoning.

In a large provincial town a patient in a charity hospital was ordered to take tincture of digitalis with tincture of strophanthus, the quantity dispensed being 40 grammes (1½ oz.). These large quantities were dispensed partly from economical motives, because two bottles containing 20 grammes each cost nearly twice as much as one bottle containing 40 grammes, and partly because the man was suffering from uncompensated heart failure, so he would have to take the medicine for a considerable time. It happened, however, that the patient, who was an uneducated person, thought fit to drink the whole bottleful at once, in order to be "quickly cured," and this he did when the nurse had left the ward for a few minutes. In about an hour he felt sick, went out of the ward, vomited, and afterwards proceeded to the water closet, where he was found dead in the course of ten minutes or so. At the inquest the police pathologist stated that the man died from syncope. The internal organs were sent to the forensic laboratory for chemical analysis, but the experts there could not satisfy themselves that poison was present in a quantity sufficient to cause death. Notwithstanding this evidence the physician of the ward and the nurse were charged with manslaughter by carelessness. The court was of opinion that a drug which contained poison ought to be kept in a special poison receptacle, as directed by the hospital rules, but this the accused neglected, and therefore they were responsible for the death of the patient. Evidence was given that it would be impracticable to keep such drugs as tincture of digitalis in a special receptacle perpetually locked up. It was shown that in this case the patient being a man of advanced age with an incurable disease might die suddenly from heart failure, and this was the more probable as he had already vomited up his medicine. On account of mitigating circumstances both the physician and the nurse were acquitted, although the public prosecutor appealed to the higher court in support of his contention that they ought to be punished.

Feb. 8th.

Indian Medical Service are being strongly advocated in a certain section of the Indian press:—(1) The military and civil departments to work entirely independently of each other, and to do away with a system under which all the more lucrative civil posts are filled by members originally recruited for military service; (2) all important Government appointments to be whole-time ones, thus offering more favourable conditions for the establishment of private practitioners; (3) professorial appointments to be recruited directly from England; and (4) improving the present conditions of the subordinate services, both civil and military, as regards pay, &c., and opening up a few more higher appointments to both classes.

Ootacamund.

This queen of hill stations in India is at last to have an improved slaughter-house on a better site. The Government has decided to give Rs. 25,000, equal to the cost of constructing slaughter-houses to the design and scale of the existing buildings, provided the latter and the present site on which they stand are handed over to Government. The plans and estimates for the new buildings amount to Rs. 43,900. The council has deferred acceptance until it has the opinion of a competent authority. The council, has brought forward proposals for a new reservoir for an additional supply of water, but the sanitary engineers have replied that the existing supply should be first fully utilised.

Jan. 7th.

Obituary.

JULIA COCK, M.D. BRUX., L.R.C.P. IREL., L.R.C.S. EDIN.,

CONSULTING PHYSICIAN TO THE NEW HOSPITAL FOR WOMEN, AND DEAN OF THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

THE death of Dr. Julia Cock occurred on Feb. 7th after a long illness.

Julia Ann Hornblower Cock was born at Shrewsbury in 1860. Early in life she felt the need of a wider sphere than that of home for developing her powers, and she found her opportunity in 1877, when she joined the group of pioneer women who were opening the medical profession to their sex. She came to London in that year and entered as a student at the London School of Medicine for Women, which had at that time only recently been founded. Here she worked for five years, and obtained various distinctions, including the prize in Medicine. At that date the only registrable qualification open to medical women was that of the Licence of the Royal College of Physicians of Ireland; she obtained this qualification in 1882, and at the same time the Licence of Midwifery from the Rotunda Hospital, Dublin.

Miss Cock then settled in Braintree, where she acted as medical officer to the Braintree and Bocking Cottage Hospital, and at the same time she was resident medical officer at the Sunnyfield Convalescent Home. In 1889, when a qualification in surgery as well as in medicine became necessary in consequence of the change in the law, she became a Licentiate of the Royal College of Surgeons of Edinburgh, and, possessing then a double qualification, in 1890 she passed the examination of the M.D. Brussels with honours.

In 1887 Miss Cock was appointed a member of the out-patient, and in 1892 of the in-patient, staff of the New Hospital for Women. For 23 years the interests of her professional life centred round her work as visiting physician to the hospital. She was an accurate observer, her ardour for scientific research was exceptional, and she was an admirable clinical teacher. Although no medical school was attached to the New Hospital, there was keen competition among the students and young graduates for clerkships in her wards, and her high standard of work and her enthusiasm inspired generations of medical women. She gave them as an ideal the aspiration to record faithfully and possibly to be able to add some small contribution to medical knowledge. The equipment and the development of the pathological department of the New Hospital for Women owed much to Miss Cock.

For 15 years Miss Cock acted as joint lecturer in medicine at the London (Royal Free Hospital) School of Medicine for Women. Her administrative ability was recognised early, and for many years has been of inestimable service in the medical school. For 11 years she held office as dean of the school, and previously she had worked for many years in the capacity of sub-dean in coöperation with Mrs. Garrett Anderson, who was then dean. The welfare of the school was constantly in her mind, and the high place it has taken in recent years is largely due to her wise statesmanship. She devoted herself heart and soul to its interests, and this at a time when the burden of debt arising from the extensive building operations needed all the care possible; and it may be taken as a measure of the success of her administration that when she has been compelled by death to relinquish the arduous duties of the post of dean the medical school is free from debt. Her loss will be severely felt in the carrying out of the difficult tasks of reorganisation rendered necessary by the suggestions of the University of London Commission. One of her chief aims in the administration of the school was to encourage self-government among the students and the spirit of freedom and sense of public duty. She wished the school life to fit the students to take their part later in public and professional life—in other words, to train them in citizenship. There were hardly any rules in the school, but she instituted the offices of students' representative, both in the hospital and the school, by which the students themselves elected one of their body to be in special communication with the dean, and so to take a share in the government of the school. Later, she instituted the students' council, a representative parliament of the students in which all school affairs were fully discussed. For many years she was president of this council. One of the last projects which she had in mind was the reorganisation of the students' union on a wider basis and on more permanent lines. She attached great importance to the training of medical students in order to develop a wider outlook on life. She never sought for or encouraged personal intimacy with the students, but no student who sought her advice failed to find sympathy and understanding. She attached little value to popularity or to professional success except from the scientific point of view.

She held several other medical posts; she was medical examiner for the Board of Education; medical examiner of female proposers for Government Insurance; medical inspector of the North London Collegiate School for Girls and of the Camden School; and she was a past president of the Association of Registered Medical Women. Miss Cock made several contributions to medical literature; she wrote a memorandum on the medical inspection of secondary schools for girls, published in the Reports of the Royal Commission on Secondary Education. The article on Rheumatoid Arthritis in the Encyclopædia Medica was also from her pen; and amongst many interesting cases published was one case of malignant endocarditis in which the gonococcus was present in the blood and tissues. Her chief clinical work was on the digestive system. She was a pioneer in this country of the medical inspection of schools, of the importance of which she was firmly convinced many years before it was generally accepted.

In private life she was greatly loved and honoured, and her loss is deeply mourned by many personal friends.

"Audi alteram partem."

THE TREATMENT OF INCIPIENT AND UNCONFIRMED INSANITY.

To the Editor of THE LANCET.

SIR,—It is with great interest I have read Dr. Robert Armstrong-Jones's paper on the Treatment of Incipient Insanity and the discussion that followed, and this morning the perusal of your leading article and the letter from Dr. H. Rayner decided me to place before you the views of one who for 40 years has been treating cases of mental disease in private houses and in an asylum. Some thirty years ago I wrote a book on this very subject, and with his special permission it was dedicated to the man who had the care of the insane so much at heart—the late Lord Shaftesbury, who I may say had every sheet of the book before him, and who made certain corrections therein before he allowed his name to appear on the dedication page.

I have always maintained, and can bring abundant evidence to prove my assertion, that a large number of early cases of insanity have a far greater chance of getting better in properly managed private homes with suitable companionship and with skilled medical supervision than in our large asylums for the insane, wherein individualism is so much lost and where, to a very large extent, patients are herded in large numbers together.

To prove my contention I may point out the fact which Dr. Armstrong-Jones overlooked—that in spite of the far more humane treatment of the insane, in spite of the palatial buildings erected for their reception, and in spite of the large increase in the region of pathological research in our asylums, the regrettable fact exists that the percentage of recoveries in these institutions is less to-day than it was in the decade of 1860–1870. Some few years ago there was a very bitter feeling between those engaged in the treatment of mental disease and the neurologists. The public were beginning to feel that to go to a mental specialist meant but one advice—certification and an asylum—and this they dreaded, and to the neurologist they appealed, and the patients were treated by them in private houses and in homes. Occasionally we heard of disasters, caused in the majority of cases by inadequate supervision, but we did not hear of the many cases that got well without the necessity of certification or asylum treatment. To-day I believe I am right in saying that many of our leading mental consultants are as opposed to immediate certification of patients as were the neurologists of ten years ago.

It is therefore as clear as daylight that the law as it at present exists regarding the treatment of the insane is in many cases evaded, and it may be, as Dr. Armstrong-Jones points out, that many incipient cases are housed in surroundings not suitable, with inadequate supervision, and with no proper safeguards as to proper and kind treatment; but surely Dr. Armstrong-Jones knows there are many medical men and others with experience in this class of case who can be relied upon to do their duty by patients entrusted to their care, and whose work would be greatly lightened and their anxieties much lessened if such an Act as has so long been suggested could be brought into being, and notification of such cases for six months' treatment take the place of the present hated system of certification. This notification would be to the Commissioners in Lunacy, who would have the right of visitation, and no doubt those medical men who were known to have special knowledge and special provision for such treatment would be allowed to take a few such notified cases. I am satisfied that the hatred of certification and the dread of doing an illegal action is at the present day a great cause of early cases not being placed under proper care quickly enough. I firmly believe if such notified cases came into the statistics of the Blue Book of the Commissioners in Lunacy the recovery rate of insanity would soon be greatly increased.

With regard to the poorer classes, it is to my mind incomprehensible that the voluntary boarder clause has not been extended to county and borough asylums. I have long urged this in committees I have sat on and in many discussions in which I have taken part.

I am, Sir, yours faithfully,
LIONEL A. WEATHERLY, M.D.Aberd.

Bournemouth, Feb 7th, 1914

MADRAS CITY WATER-SUPPLY.

To the Editor of THE LANCET.

SIR,—In your leading article of Jan. 31st on Major S. P. James's paper *re* "Protection of India from Yellow Fever" you call attention to the evils of intermittency of public water-supplies and domestic storage of water, and class Madras City with ports demanding storage for 24 hours in certain of its limits, "pressure being only put on for a short time daily." The Madras water-supply is a gravitation system, the distribution of which has been extended to excess to meet the needs of a rapidly increasing population. Hence, during the hours of maximum demand, there is a portion of the city at the periphery of the system which obtains a mere dribble. My object in drawing attention to a trivial variation of your account, and your rightly pointing the moral that the authorities of these ports should waken up and remedy mistaken modes of supply, is to state that Madras City is in the act of putting matters right.[1]

I would add that this is not an instance of "The Sanitary Awakening of India" (a period practically limited to 1911–13, according to a recent author), but of what that euphemism means—namely, where the attention of anyone who is ignorant of this most interesting and well-investigated epidemic, or the System of D'Arcy Power and Murphy may be consulted, but the literature is too abundant even to epitomise.

---

[1] All India Sanitary Conference, Madras, November, 1912. Paper by J. W. Madeley, M.A., M.I.C.E., &c., Special Engineer, Corporation of Madras.

I regret that the word "involution" in the term "involution forms" should have puzzled Mr. Ross, or that he should have consulted a dictionary which told him that the word meant "involved." It is one which is in everyday use amongst bacteriologists to denote a phenomenon with which they are perfectly familiar. Had Mr. Ross consulted Muir and Ritchie's "Bacteriology," or almost any elementary text-book on the subject, he might have learnt what the word means. If any pathologists use the word loosely, to mean something which they do not understand, I leave them to his mercy.

I did not deal with the prevention of syphilis in my article, because it was not an article on the prevention of syphilis. Prevention may be better than cure, but it does not follow that the question of cure may not be worth the attention of medical men who may be called on to treat the disease any day of their lives.

I suspect that the reason why I am submitted to this catechism is my statement that I see no reason for assuming any form other than that of a spirochæte in the life-history of the organism of syphilis. Most pathologists would, I think, have made a very much more definite pronouncement on the subject, but my remark (which was very carefully considered) appears to me not only true but self-evident. To realise this, make a similar series of statements about tubercle. The tubercle bacillus occurs as a bacillus in tuberculous lesions of all sorts and at all stages. It can be cultivated outside the body for many generations, during which (except for a few occasional bodies which are probably involution forms) it remains a bacillus. Therefore, there is no necessity for assuming any other form in its life-history. If Mr. Ross asks "Why?" to this statement I am afraid I can only say that it is a matter of logic. His analogy of malarial crescents is entirely beside the point unless he has cultivated the crescents for many generations outside the body, and has reproduced the disease with the pure cultures.

Lastly, with regard to his statement that the best way to prevent syphilis is to find out the exact truth concerning the parasite which causes it, I must point out that we have a method which is tolerably efficacious in the prevention of small-pox, although our knowledge of the organism which causes that disease is singularly deficient.

I am, Sir, yours faithfully,

Harley street, W., Feb. 9th, 1914. W. D'ESTE EMERY.

THE TUNING-FORK IN THORACIC DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—I understand that Mr. James Cantlie has been using a tuning-fork as a means of diagnosing enlarged organs, or effusions into the pleura, and the like. Allow me to say that this is not a new idea. I have applied a tuning-fork in exploring the chest for many years, the notion first coming to my mind after reading the late Dr. Stone's lectures before the Royal College of Physicians some time back in the "eighties," if my memory serves.

A tuning-fork is of great assistance in examining the chest, but it is especially advantageous in marking out lung cavities or dilated tubes. Even in these conditions certain physical factors, such as the presence of much fluid or of pus, will lessen the diagnostic aid of the fork. But when a cavity is dry the reverberation of the dominant note is distinctly increased over the cavity, and is diminished as the instrument is carried away from the lesion. Again, in men with hard, almost solid, ribs the sounds are better conducted, as one would expect, than in children and young people with more elastic ribs, which are not such good conductors.

One point I have observed. Different cavities have different dominant notes, and therefore respond varyingly to a fork in G or in C or other note. This I believe is in accordance with the experience of speakers, clergymen and others, who have to address audiences in large halls, churches, or cathedrals. If the voice is pitched to the dominant note of the building the speaker is heard at the periphery, but if he speaks on an unsympathetic note he will only be heard with distinctness at a short distance, even though he should almost shout.

I am, Sir, yours faithfully,

London, Feb. 7th, 1914. SEYMOUR TAYLOR.

A NATIONAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I ventured to make a few remarks in your issue of Jan. 31st on the free choice of doctor because THE LANCET, the *British Medical Journal*, and the *Morning Post* had all laid so great a stress upon it; but surely in discussing the *pros* and *cons* of a State Medical Service there are other and bigger questions beside which "free choice" becomes comparatively insignificant.

No medical man will, I feel sure, deny that there is a great wastage of life through death or permanent disability from preventable or postponable disease, and no one will deny that the physique of the nation is faulty and not what it might be. Further, the birth-rate is declining to a somewhat alarming extent, and consequently the conservation of the health of those who are born is becoming a matter of vital importance to the prosperity of the nation. The question is whether the present method of bringing the public into touch with the medical profession is as good as it could be, or whether by some change the standard of the national health and physique could be raised.

There have been enormous advances in medical knowledge and methods of diagnosis and treatment which have been of great value to individual patients, but so far have done but little to prevent disease and raise the standard of the health of the community as a whole. Rightly or wrongly, it seems to me that these very advances have put the science of medicine beyond the power of individual effort to deal with, and that for the sake of the nation individualism and competition should give way to coöperation. Again, rightly or wrongly, it seems to me that the only way to obtain whole-hearted coöperation within the profession and to extend to the whole nation the advantages of the recent advance in medicine and allied sciences is to establish a whole-time salaried State Medical Service, with prevention of disease as its chief object. It is from this point of view that I would like to see the question of State Medical Service *versus* the present panel system discussed; therefore I shall only answer Dr. Lauriston Shaw's and Dr. Major Greenwood's letters in so far as they raise the question of the possibility of free choice of doctor under a State service—a question which is thought by many to be of vital importance.

In discussing the possibilities of a free choice of doctors under a State service it must be remembered how limited is the freedom of choice to-day. Poor-law patients, dispensary patients, and hospital patients have practically no choice, and until a year ago club patients had none. In country towns the choice is strictly limited, and in "unopposed" practices there is none. Financial and geographical considerations limit the choice of even better-class patients, whilst amongst the very poor the cheapest doctor is of necessity invariably chosen. Many of these limitations would necessarily continue under any conceivable system of State service. As I have stated elsewhere, I can see no reason why the present system of allotting patients should be discontinued if to-morrow the 20,000 panel doctors became whole-time salaried officers under the State. At first there would be discrepancies with regard to the numbers on each doctor's list, but things would soon adjust themselves to altered circumstances. There would have to be, as there should be now, some limit put upon the work each man was called upon to undertake, which could be done by limiting the number of persons on each list, say, to 3000. When a doctor's list had reached this number other patients choosing him would have to be put upon his waiting list until vacancies occurred, and in the meanwhile go to the doctor of his next choice. After all this is much what happens now. There is a limit to every man's capacity for work, and when that limit is reached would-be patients are either refused or handed over to a partner or assistant. The panel system thus adapted to a whole-time salaried service and open to all would extend "free choice" to many who have not got it now, including the Poor-law patients; and pending the establishment of a fully organised State service it seems to me quite a feasible scheme.

A fully organised State Medical Service, including all branches of the profession, allied sciences, hospitals and other institutions, nursing and dispensing, must necessarily evolve slowly, and it is difficult to forecast the exact form it will ultimately assume. However, I picture in my mind the hospitals greatly increased in number and made the centres of all medical activities. To each hospital will be attached senior, junior, and assistant general practitioners, who will be as integral and essential a part of the hospital staff as any other branch of the profession, and according to my vision will be paid grade for grade equally with physicians, surgeons, and specialists. As members of the staff general practitioners will be able to keep in touch with their patients and themselves do for them many things which they cannot now do in cottages and workmen's dwellings. As members of the staff they will have the advantage of being in daily touch with representatives of all other branches of the profession, which will add greatly to the interest of their work. Each member of the staff of general practitioners will have his definite hours on duty for seeing patients at the hospital, instead of as now at his own private dwelling, and a list of the staff with their hours of attendance will be posted up in the hospital and published weekly in the local papers. All patients who are able to leave their homes will thus be able to come to the hospital and seek the advice [illegible] choice, whilst those who [illegible] illness will send or telep

ask the doctor of their choice to visit them. If the chosen doctor on that particular day has already filled up all the available hours of his time on duty the patient will have to be content with one of the assistants or ask the senior of his next choice to take up his case, just as now happens in private practice.

In the smaller towns there must be outposts in the shape of cottage hospitals worked on the same lines as regards "free choice" and linked up with the bigger centres by means of telephone, motor-cars, and motor ambulances. In the rural districts there must be dispensaries, linked up in their turn with the cottage hospitals, at which the local doctors will have their consulting-rooms well equipped with instruments and all modern appliances, and with a nurse or nurses to help them in their work. In such districts as require more than one doctor some choice can be given to patients.

It is some such system as this for which advocates of a State Medical Service are working, and it would give as great a freedom of choice of doctor as there is now, and it would extend that freedom to a larger proportion of the population. But it is probable that as the work of the service became, as it is bound to do, more and more specialised, as each branch of the profession worked more and more in close coöperation with every other branch; and as modern methods of diagnosis and treatment became more and more scientific and exact and available to all, the desire for "free choice" would gradually die a natural death. It is even possible that in the days to come advancing knowledge will throw more light on those diseases now classified as neurotic and point to a better and more scientific way of dealing with them than by "faith in the doctor."—I am, Sir, yours faithfully,

CHARLES A. PARKER.

Upper Wimpole street, W., Feb. 9th, 1914.

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—If the definition of language be the art of concealing thought, Mr. Lloyd George is to be congratulated on his statement at the complimentary dinner to Dr. Addison on Friday last that "excluding duplicates in any one Insurance area, but including doctors whose names are put on more than one panel," there are over 20,000 practitioners on the panels. A superficial comparison of the panel list for London with those for the surrounding counties shows immediately that a fallacy of the first magnitude lies concealed in the specious phrase quoted above. On every boundary of every contiguous county or insurance area duplicates are counted, "and there are several," though pains are taken to state that duplicates are not counted within the interior of these same areas. Had this been done, which would have been equally justifiable, Mr. Lloyd George might have had the satisfaction of stating that there are more practitioners on the panels than are contained on the Medical Register.

The correct figure is probably about 14,000, as has been previously stated.

I am, Sir, yours faithfully,
ROBERT CARSWELL,
Honorary Secretary, National Medical Union.

Strand, W.C., Feb. 10th, 1914.

To the Editor of THE LANCET.

SIR,—The *East Anglian Daily Times* is never tired of singing the praises of the Insurance Act, extraordinary measure. A very remarkable statement was made at a recent meeting of the East Suffolk Insurance Committee by the vice-chairman, but it was not reported in the *East Anglian Daily Times*. He said: "Had I been a doctor nothing would have induced me to sign the agreement." He referred to the 1914 agreement. Comment is, I think, unnecessary.

I am, Sir, yours faithfully,
T. CUMING ASKIN, M.D. Dub.

Alderton, Woodbridge, Suffolk, Feb. 7th, 1914.

To the Editor of THE LANCET.

SIR,—There is no doubt that the profession is drifting hopelessly with the tide. General practitioners are divided into two hostile camps with no possibility of reconciliation. The Presidents, past and present, of the Royal Colleges give no advice or help. Some other distinguished doctors' names are to be found on the committee of a recent dinner in honour of a man who probably is an important factor in the division. The real cause has been the weakness of half of the medical profession in signing a pledge and then breaking it at the beginning of last year.

These doctors are apparently busy forming societies to support panel practice. They can save themselves the trouble; being Government servants, and badly beaten on their own ground, they are never likely to obtain reforms worth speaking of unless they organise a strike, and even then, after last year's fiasco, no one will heed their threats. The politicians, medical and lay, have won the day, and unless something is done I have no doubt that the insurance doctors will submerge themselves (as they have done in Germany) to the level of underpaid artisans.

It may be asked, Is there any remedy for the present chaotic condition? It is a fact that a certain amount of contract medical service is required in this country; for instance, a labourer with six children earning 30*s.* a week cannot afford to pay a doctor's bill; for these a Public Medical Service ought to be provided. But it must be organised and run entirely by the medical profession, its discipline especially must be in our own hands, and it must be a severe discipline. Such a service can and ought to be formed. It would be voluntary, and the patients would have free choice of doctors and all the petty annoyances of the Insurance Act would be swept away. No doctor would feel ashamed to belong to it. Politicians would be deleted from its council, and with their removal two-thirds of the trouble of organisation would disappear. I am, Sir, yours faithfully,

Streatham, S.W., Feb. 7th, 1914. E. H. WORTH.

A CATALOGUE OF SUFFERING.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "M.D. Cantab.," I can assure him that closer attention will be given in future to the manner of setting forth to subscribers the disabilities of candidates for election to that great charity, the Hospital for Incurables, Putney.

No efforts are spared by the board of management to ensure that the disability of a candidate for election is incapable of cure or even of improvement. The list of selected candidates represents a very small proportion of the total number of applications for the benefits of the charity. With further generosity on the part of the public its work could, of course, be considerably extended.

I am, Sir, yours faithfully,
A MEDICAL MEMBER OF THE BOARD OF MANAGEMENT.

Feb. 5th, 1914.

THE NATIONAL INSURANCE ACT.

MEMORANDUM WITH REGARD TO PERSONS MAKING THEIR OWN ARRANGEMENTS UNDER SECTION 15 (3) OF THE NATIONAL INSURANCE ACT.

A MEMORANDUM has been issued by the National Health Insurance Commission in which the Commissioners draw the attention of the Insurance Committees to certain provisions in the current Medical Benefit Regulations as regards persons making their own arrangements, in which those Regulations differ from the Regulations previously in force.

The memorandum in paragraphs 2–6 deals with persons who were allowed to make their own arrangements for medical benefit during the past year, and explains their position when they have not given the proper notice of their desire to change their method of obtaining treatment. Such persons are to be deemed to have applied to obtain treatment in the current year in the same manner as in the preceding year. Insurance Committees will have to review the individual cases, for which purpose a proper form has been provided for issue, and where a committee consider that they must refuse a permission previously granted, the insured person will revert to the ordinary arrangements.

Paragraph 7 of the memorandum explains the position of exempt persons who are required to make their own arrangements. A form has been prepared, which can be issued by Insurance Committees, and which is also applicable to other persons who by the operation of any income limits fixed by the committee are required to make their own arrangements.

The next ten paragraphs deal as follows with—

Persons making their own Arrangements otherwise than with Duly Qualified Medical Practitioners.

8. It is within the knowledge of committees that the old Regulations did not deal under expressly separate provisions with arrangements made with qualified practitioners and those made with other persons. It was, of course, contemplated that the great majority of applications under Section 15 (3) of the National Insurance Act, 1911, would be received from persons desirous of making private arrangements with qualified practitioners; and this expectation has, it is understood, been justified by the experience of committees, who will, in all probability, continue to receive the bulk of their applications from persons desirous of making arrangements of that nature. But the Regulations did not exclude the possibility of arrangements of another class, and it was left to Insurance Committees to consider the particulars of individual applications with a view to giving or withholding consent, in accordance with a proper exercise of their discretion, upon the merits of each case.

9. It is understood, however, that difficulty was experienced last year by committees in some cases in dealing with the applications of persons desirous of arranging otherwise than with qualified practitioners, practically the whole of which have, according to the Commissioners' information, been received from those who wish to obtain treatment from persons known as "herbalists," on grounds of preference based either on a long existing habit, or on some objection to the treatment given by qualified medical practitioners. In the course of their consideration of these cases it is believed that doubts have occurred to Insurance Committees as to whether their discretion was not fettered by the terms of the

Regulations, as appearing to suggest, in the absence of any specific appropriate provision that, failing the satisfaction of the standards applicable to the case of treatment by qualified practitioners, the committee were not empowered to consent to, or contribute to the cost of, arrangements for other kinds of treatment.

10. It is not the case, in the opinion of the Commissioners, that the old Regulations fettered the discretion of Insurance Committees in the manner suggested; and it was open to them, as the Commissioners have advised when consulted, to exercise that discretion upon the merits of each application before them in accordance with their duties to the insured persons concerned. But as confusion seemed likely to arise in the consideration by committees, under one provision of general application, of cases differing so widely in character, and as situations of difficulty would certainly be created by an indiscriminate adoption, in respect of all types of cases, of administrative procedure primarily devised with a view to the circumstances of treatment by qualified practitioners only, the Commissioners have, both for the purpose of removing doubts and for the administrative convenience of committees, amended the Regulations in making them substantive, so as to restate (in Article 44) their practical effect in the form of distinct and separate provisions governing, in the two sets of cases, the conditions to be observed and the circumstances in which a contribution may be made.

11. Before, however, these provisions are dealt with, it should perhaps be pointed out that, though the conditions of the Special Exchequer Grant are no longer specifically referred to in the Regulations as conditions of a contribution by the committee, the position is in no respect modified by this amendment. The conditions in question are still required to be complied with as conditions of the Exchequer Grant *to Insurance Committees*; and *in the event of any* breach of these conditions in connexion with treatment privately arranged for under Section 15 (3) of the National Insurance Act, 1911, the committee will be liable to a proportionate diminution of their share of the grant. Moreover, paragraph 4 of Article 44 now expressly provides, in such cases, for a reduction being made in the contribution which would otherwise have been payable under that article to the person, in whose case non-fulfilment of the conditions has occurred, of the amount of the loss occasioned thereby; and as this provision is one of general application, the effect is that *in the case of every person* making his own arrangements, the committee's contribution is liable to be reduced by the amount payable from the Exchequer in respect of his treatment, unless the conditions of the Exchequer Grant have been fully complied with.

12. Proceeding now to the separate provision governing private arrangement cases with qualified practitioners, it will be observed that the previous position is not materially modified by the new Regulations. The committee are required to satisfy themselves that the private arrangements made "are such as to secure treatment (including drugs and appliances) not inferior in nature, quality, and extent to that provided under the arrangements made by the committee." They will also, of course, secure compliance with the conditions of the Exchequer Grant, as having general application to all cases, in the manner indicated in the preceding paragraph.

13. It should perhaps be pointed out that the Regulations have been slightly amended as to the methods according to which the committee's contributions are to be calculated. It is now possible for the committee to contribute to the cost of arrangements for receiving treatment from a qualified practitioner, made in either of the following ways—namely: (1) As regards both treatment and the supply of drugs, &c., by contract at a fixed rate or rates; (2) as regards treatment alone, by contract at a fixed rate, drugs, &c., being obtained when required, and accounts therefor being presented to the committee; (3) as regards drugs, &c., alone, by contract at a fixed rate, treatment being obtained when required and accounts presented; and (4) both treatment and drugs being obtained when required and accounts presented.

14. With regard to the separate provision (paragraph 2 of Article 44) governing private arrangements for receiving treatment otherwise than from qualified practitioners, it will be seen that it contains no explicit requirements as to the manner in which the committee are to satisfy themselves as to the arrangement made. It will, of course, be obvious that any definite standards established, such as that prescribed in the case of treatment by qualified practitioners (paragraph 1 of Article 44) must be comparative, and must thus fail to apply where the circumstances are not comparable; and it will therefore not be possible for the committee to judge of the satisfactoriness of any arrangements made with unqualified persons by the standards applicable to the panel system.

15. Paragraph 2 of Article 44 accordingly leaves the matter at the discretion of the committee, who "may make such contribution ...... as they think fit." But private arrangements with unqualified persons, like all other private arrangements, are subject to the application of the conditions of the Exchequer Grant. These conditions require, *inter alia*, that the person undertaking treatment should also undertake to provide domiciliary treatment for tuberculosis, in accordance with the Local Government Board Order of July 26th, 1912; and as it is not legally open to any person other than a duly qualified medical practitioner to perform this service, it is clear that no arrangements otherwise than with qualified practitioners could earn the grant to which these conditions attach. The committee will not therefore be able to rely upon receiving any sum from the Exchequer Grant in respect of treatment afforded by unqualified persons; and they would be well advised, in the Commissioners' opinion, to make it clear to any person desirous of being so treated that, in the probable event of a reduction in their share of the grant, the maximum sum available to them for contribution would be limited to the sum (amounting, with the State proportion, to 6*s.*) which is payable in respect of the applicant by his Approved Society or out of his account in the Deposit Contributors Fund, or from the Exempt Persons Fund, as the case may be.

16. *It will be seen that the Regulations only admit of a* contribution being made by the committee to the expense of arrangements for treatment by an unqualified person if the insured persons pay at a fixed capitation rate. The difficulty of equating the value of services rendered under widely varying systems, with a view to the adoption of a scale for the calculation of contributions on an attendance basis, would in practice prove almost insuperable.

17. The provisions of the old Regulations, enabling the committee in these cases to reduce or withhold their contribution in the event of their receiving representations from an Approved Society that the treatment is not such as will adequately protect the society's funds, is retained in the Regulations now current.

The Commissioners point out in conclusion that the forms for use by committees in connexion with applications from persons desiring or required to make their own arrangements, will have to be revised, and model revised forms have been prepared. Forms 43/I.C. and 43(*b*)/I.C. will be used in the appropriate circumstances where the arrangements are proposed with duly qualified practitioners. Form 43(*c*)/I.C. will be used in the case of persons required to make their own arrangements either under Section 9 of the National Insurance Act, 1913, or by the operation of any income limit adopted by an Insurance Committee. In view of the "Travellers" arrangements now in operation, it is not thought that committees will require any form similar to the original Form 43 (*a*.)/I.C., but in the event of such a form being necessary advice will be given by the Commissioners. Similarly, on application, advice will be given to Insurance Committees requiring forms to meet the case of insured persons, who desire to make their own arrangements with an unqualified person.

THE INSURANCE AND LOCAL MEDICAL COMMITTEES FOR KENT.

THE newly elected Local Medical Committee and Panel Committee for Kent are trying to arrive at their own solution of the administrative conditions imposed upon them by the National Insurance Act.

Congress will be 30*s*., and for members of their families accompanying them 15*s*. Messrs. T. Cook and Son, of Ludgate-circus, London, E.C., have been appointed official hotel and travel agents. A museum, the scope of which has already been outlined in these columns, is being arranged by a committee of which Mr. Hopewell-Smith is chairman and Mr. F. N. Doubleday is honorary general secretary. Intending exhibitors should apply to the offices of the Congress, 19, Hanover-square, London, W.

University of Liverpool.—Dr. Warrington Yorke, director of the Runcorn Research Laboratory in the Liverpool School of Tropical Medicine, has been appointed Walter Myers Professor of Parasitology in the University of Liverpool.

The late Mr. J. H. Targett, F.R.C.S., obstetric surgeon to Guy's Hospital, who died on May 26th last, has left by his will a sum which will bring in approximately £300 per annum towards the upkeep of the new Pathological Department of Guy's Hospital.

Centenarians.—Miss Ritso, of Bath, celebrated the 102nd anniversary of her birthday on Jan. 26th.—Mrs. Ann Peters, who celebrated the 100th anniversary of her birthday on Dec. 29th last, has died at Great Bookham, Surrey.

Devon and Cornwall Ear and Throat Hospital, Plymouth.—At the annual meeting of the Devon and Cornwall Ear and Throat Hospital the committee accepted with much regret the resignation of Mr. George Jackson, who has been honorary surgeon to the charity since the foundation of the hospital 27 years ago, and he was unanimously appointed honorary consulting surgeon.

Royal United Hospital, Bath.—The annual meeting of the subscribers of the Royal United Hospital, Bath, was recently held under the presidency of the mayor (Dr. Preston King). The medical report was satisfactory. The financial statement showed that the total income was £5289 and the total expenditure £7818, showing a deficit balance of £2529. The committee make a strong appeal for increased financial support.

Presentation to a Medical Man.—On Feb. 4th a presentation of a pianola was made to Mr. George Potts, of Maidstone, on behalf of the medical practitioners of Kent, by Mr. Arthur Maude, chairman of the Kent Medical Committee, in recognition of the valuable services which Mr. Potts has rendered during the last two and a half years as honorary secretary of the Kent Medical Committee.

Child Study Society, London.—This society has arranged the following programme of lectures and discussions for the present session, on Thursday evenings at 7.30 o'clock, at 90, Buckingham Palace-road, S.W. On Feb. 19th Mr. E. W. Scripture, of New York, will lecture on Speech Defects in Children and their Treatment; on March 5th Miss C. C. Graveson will lecture on the Sense of Humour in Children; on March 19th Professor J. J. Findlay will lecture on the Dramatic Impulse in Children; and on April 2nd Dr. Leonard Guthrie will lecture on the Nervous Child. On April 23rd there will be a joint meeting with the Charity Organisation Society, when the Rev. J. C. Pringle will open a discussion on Raising the Standard of Child Upbringing. On May 7th there will be a joint meeting with the Parents' National Education Union for a discussion on Education in Early Childhood before School Age.

"Jubilee" Congress of the German Roentgen Society.—This society will celebrate the tenth year of its existence by an extended congress and comprehensive exhibition to be held in Berlin from April 19th to 21st next. The particular time has been chosen so that visitors to Berlin for the Orthopædic and Surgical Congresses may have an opportunity to attend. A paper will be read by Dr. Krause, of Bonn, upon the Biological Effects of the Roentgen Rays upon Animal and Human Tissues. Particulars of other papers and demonstrations which it is proposed to offer must be sent to the secretary, Dr. Immelmann, Lützowstrasse, 72, Berlin, W. 35, at the latest before March 15th. Members are reminded that tickets of membership can be obtained (subscription M.10) up to April 1st from Herr Melzer, Ziegelstrasse, 10-11, Berlin, N. 24. The sessions and exhibition will take place in the Landes-Ausstellungspark, Berlin, N.W., at the Lehrte railway station (entrance in the Alt Moabit-street 4-10). The president for the year is Dr. Max Levy-Dorn. The first session takes place on Sunday, April 19th, at 10 A.M.

London Hospital.—The Worshipful Company of Grocers have made an offer to the Governors of the London Hospital of a sum not exceeding £10,000 for the provision of accommodation for the treatment of patients suffering from syphilis.

BOOKS, ETC., RECEIVED.

Notes, Short Comments, and Answers to Correspondents.

LIBERIA'S ENERVATING CLIMATE.

LIBERIA, the Negro Republic of Western Africa, occupies that part of the coast of North Guinea which is between the river Kavalli, S E , and Manna, N.W., a distance of about 350 miles, with an arc [illegible] the United [illegible] as an independent State. I [illegible] 050,000, including about [illegible] British Consul in the Re[illegible] whose annual report has just been received at the Foreign Office. In it he remarks: "The constantly recurring attacks of malarial fever of severe type which incapacitate the European in Liberia, handicap him in his struggle against the many discouraging conditions by which he is surrounded, and, at the end of an absurdly short period of service, send him back to Europe for indispensable recruitment at the expense of time, money, and business [illegible] ctically avoided if European [illegible] e small amount of trouble and [illegible] xpense involved in mosquito- [illegible] l dwellings. This is a vital [illegible] apparently, in spite of the constantly reiterated advice of the schools of tropical medicine, has as yet thought of taking. In common with all the coast lands of West Africa, Liberia abounds with mosquitoes, and the resultant fever is as common as it is disastrous. It is safe to say that throughout the country there is only one building which is proof against mosquitoes—namely, this Consulate-General—and although the result of the experiment has been striking in the extreme, it has not been further adopted, with the result that incapacity of employees and consequent dislocation of business from various forms of fever are matters of daily occurrence The climate of a tropical country with an annual rainfall of probably more than 160 inches requires but litt[illegible] is bound to be as bad, as [illegible] as it can be, and when [illegible] is sapped by the ravage[illegible] European is indeed in an unhappy case The food supply of Liberia is so bad and insufficient as to have provoked the remark of a well known resident that 'whilst he resided in Liberia he boarded in Europe.' This is by no means an exaggeration. In Monrovia (the capital), for example, the population have to depend upon supplies brought by the fortnightly fast steamers of the Elder Dempster group of companies. At times it is possible to obtain a little more or less fresh meat from a cargo boat, but, in any case, due to want of cold storage, butcher's meat is a luxury which can only be partaken of during a very few days in each month, whilst fresh milk and butter are unknown Cattle, sheep, and goats thrive, but no attempt is made to establish an abattoir, dair[illegible] that [illegible] tain [illegible] of [illegible] fowls, suffers severely.'

A PASSION FOR PILLS.

IN the year 1814 one man created a record by swallowing not fewer than 51,590 pills His name was Samuel Jessup, who died at Heckington in Lincolnshire in 1817, aged 65 He was an opulent grazier, a bachelor, without known relatives, and for the last 30 years of his life possessed a craving for what was then called "physic" In 21 years he took 226,934 p[illegible] of Wright, who [illegible] of 10,806 pills a y[illegible] end he took 78 a[illegible] bottles of mixture, juleps and electuaries. Some of these particulars were disclosed at a trial for the amount of an apothecary's bill at Lincoln assizes shortly before his death.

A RAT-DESTROYING SHIP.

O[illegible] (the Physician), is [illegible] William Lamb, of [illegible] statement that the [illegible] ing at Philadelphia [illegible] by an Australian medical man, Dr George Harker, for extinguishing fires on board ship by exhausting all the oxygen from the ship, but the gases formed by it are destructive to life, and this fact is now being utilised by the Government officials engaged in the crusade against bubonic plague In view of this it is stated that Philadelphia is in this respect one of the best guarded harbours in the world.

AN INK-PENCIL PEN.

Messrs. Burge, Warren, and Ridgley, Limited, of Great Saffron Hill, London, E C , have sent us one of their "Compacto" stylo pens, which they describe as "the nattiest pocket ink pencil ever made." Certainly the description is well merited. The "Compacto," which closes up to three inches for the pocket, will be found most useful for the taking of notes, as the ink dries at once, the flow being fine, though adequate for all [illegible] filling in of charts, official [illegible] space is usually limited, [illegible] question, the "Compacto" [illegible] To the medical prac[illegible] peal as a time saver in [illegible] can be obtained of any stationer or from the makers for 3s. 6d.

◆

"*Havcrstock.*"—Many details [illegible] Number of THE LANCET c[illegible] regard to the regulations [illegible] didates for admission to the Indian Medical Service. Candidates must possess, under the Medical Acts, a [illegible] Great Britain and Ireland. [illegible] e in Medicine and Surgery [illegible] (provided that professional study was begun before Jan. 1st, 1892) registrable in the Colonial List of the British Medical Register pursuant to Section 11 of Part II of the Medical Act, 1886 (*vide* p. xcvii. of the Medical Register, 1913). Our correspondent should also refer to the proceedings of the General Medical Council in THE LANCET of June 15th, 1912, p. 1629 *et seq.*, and the report by the examination committee on Indian Medical Study and British Qualifications. Further advice could be obtained from the Registrar, General Medical Council, 299, Oxford street, London, W.

Etiquette.—It is not usual, even when no "introduction" can be obtained, for the newcomer to call upon the patients whose names are on the books of the practice. On the [illegible] to call at once upon the [illegible] to inform them of his [illegible] of the usual introduction is a serious drawback

Dr A L Moreton—Sir Jonathan Hutchinson's works were announced in the advertisement pages of THE LANCET of July 26th, 1913, p 5

COMMUNICATIONS not noticed in our present issue will receive attention in our next

A DIARY OF CONGRESSES.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. Davis: Clinique (Skin). 5.15 P.M., Lecture:—Mr. W. Trotter: Common Errors in Diagnosis—Sprains and Fractures.

TUESDAY.—4 P.M., Dr. G. Rankin: Clinique (Medical) 5.15 P.M., Lecture:—Sir John Bland-Sutton: Common Errors in Diagnosis—Abdomen.

WEDNESDAY.—4 P.M., Mr. O. L. Addison: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Sommerville: Common Errors in Diagnosis—Foods and Feeding.

THURSDAY.—4 P.M., Dr. T. G. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Dr. E. Pritchard: Common Errors in Diagnosis—Infant Feeding.

FRIDAY.—4 P.M., Mr. C. E. West: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Pardoe: Genito-urinary Surgery.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: Genito-urinary Surgery.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. [illegible] Mr. B. Harman: Diseases of the Eye. [illegible] 5 P.M., Lecture:—Mr. Pardoe: [illegible]

THURSDAY.—9 A.M., Dr Bernste[illegible] ment. 10.30 A.M., Dr. Simson. [illegible] 12 noon, Lecture:—Dr. G. [illegible] 2 P.M., Medical and Surgical [illegible] Operations. 2.30 P.M., Mr. Du[illegible] Lecture:—Mr. Souttar: Diseas[illegible]

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. Souttar: Diseases of the Testicles.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). X Rays and Electrical Methods. 3 P.M., Special Demonstration: Paralysis of the Vocal Cords (Mr. Gillies). Medical In-patient (Dr. A. J. Whiting). 4.15 P.M., Lecture:—Dr. A. J. Whiting: The Treatment of Auricular Fibrillation.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on the Neuroses and Psychoses of Children:—

MONDAY.—4.15 P.M., Dr. F. Warner: Elements of Brain Training.

THE THROAT HOSPITAL Golden square, W
MONDAY —5 15 P M , Special Demonstration of Selected Cases
THURSDAY —5 15 P M , Clinical Lecture

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen square Bloomsbury, W C
TUESDAY —3 30 P M , Clinical Lecture —Dr S Scott Labyrinthine Forced Movements
FRIDAY —3 30 P M , Clinical Lecture —Dr S Scott Labyrinthine Nystagmus

QUEEN'S HOSPITAL FOR CHILDREN, Board Room of the Hospital, Hackney road, N E
WEDNESDAY —4 P M , Lecture Dr J L Bunch : Some Skin Diseases in Children

CANCER HOSPITAL Museum of the Hospital Brompton S W
Post-Graduate Lectures on the Diagnosis and Treatment of Cancer —
WEDNESDAY —5 P M , Dr Horder The Value of Combined Treatments in Cases of Inoperable Cancer

ST JOHN S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W C
TUESDAY —2 P M , Dr W Griffith : Pathology of the Skin Appendages
THURSDAY —6 P M , Dr M Dockrell Seborrhœa and Psoriasis dealt with as Stages of the Same Dermatitis in Symptoms, Diagnosis and Treatment

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Room of the Institute 37, Russell square, W C
Course of Instruction for Tuberculosis Officers School Medical Officers Medical Practitioners &c —
FRIDAY —5 P M The Diagnosis and Treatment of Tuberculosis &c — Lecture VI —Mr H J Gauvain Surgical Tuberculosis,

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle street, Piccadilly, W
TUESDAY —3 P M , Prof W Bateson Animals and Plants under Domestication (Lecture V)
FRIDAY —9 P M Prof A Keith Busts and Portraits of Shakespeare and of Burns : An Anthropological Study

MANCHESTER HOSPITALS POST GRADUATE CLINIC
MONDAY —MANCHESTER CHILDREN S HOSPITAL, Gartside-street — 4.30 P M , Mr W H Hey Surgical Cases in Children
TUESDAY —SALFORD ROYAL HOSPITAL—4 30 P M , Mr J P Buckley, Hernia
WEDNESDAY —ROYAL INFIRMARY—4 30 P M , Demonstration of Medical and Surgical Cases
THURSDAY —ANCOATS HOSPITAL—4 30 P M , Dr A Renshaw: Information derived from Blood Counts
FRIDAY —ROYAL EYE HOSPITAL—4 30 P M , Dr H H McTabb: Choroiditis

ROTUNDA HOSPITAL POST GRADUATE COURSES, Dublin
MONDAY —10 A.M , Obstetrical Lecture Rupture of the Uterus (continued) 11 A M Examination of Patients and Minor Operations
TUESDAY —10 A M , Major Operations
WEDNESDAY —10 A M , Obstetrical Lecture The Varieties of Contracted Pelvis 11 A M , Examination of Patients and Minor Operations
THURSDAY —10 A M [illegible]
FRI [illegible]

For further particulars of the above Lectures, &c , see Advertisement Pages

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub Editor "

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager "*

We cannot undertake to return MSS not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1913 were given in THE LANCET of Dec 27th, 1913

VOLUMES AND CASES

VOLUMES for the second half of the year 1913 are now ready Bound in cloth, gilt lettered, price 16*s* , carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s* , by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C , are dealt with by them ? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—Messrs WILLIAM WOOD AND CO , 51 Fifth Avenue, New York, U S A

Y.—Yost Typewriter Co., Lond.

Hunterian Lecture

ON THE

EXPERIMENTAL PRINCIPLES OF THE OPERATIVE TREATMENT OF FRACTURES. AND THEIR CLINICAL APPLICATION.

Delivered before the Royal College of Surgeons of England on Feb. 6th, 1914,

BY ERNEST W. HEY GROVES, M.S. LOND., F.R.C.S. ENG,
HUNTERIAN PROFESSOR OF THE COLLEGE; SURGEON TO THE BRISTOL GENERAL HOSPITAL.

(Concluded from p. 441.)

THE CLINICAL PROBLEM (*continued*).

The Method of Transfixing Bolts and Bolted Plates.

No metal nail or screw driven into a bone can remain tightly in position and resist a displacing force for very long unless it holds the bone by a broad flange. The most simple way of providing this broad grip is by using a bolt which transfixes the bone and is secured by a nut and washer on the opposite side.

Such a device has for a long time been advocated by Professor Depage, of Brussels, who has designed a very useful set of appliances for carrying it out, and has published many cases illustrating its use. No doubt this method is exceedingly efficient, particularly in the fixation of fragments at the articular ends of the long bones and in certain very oblique fractures of their shafts. But its efficiency can be still more increased and its scope extended if the transfixing bolts be used to fix metal plates on opposite sides of the bone. It will be convenient to describe the technique I have adopted, first for fractures of the articular ends, and secondly for fractures of the shaft.

The Bolting and Bolted plate Methods in Para-articular Fractures.

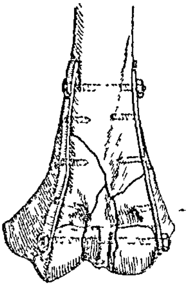
It is in the elbow, knee, and ankle that these fractures are most common and the most difficult to treat. There are two main things to be accomplished—first, the fixing of the broken fragments together, and then the firm attachment of the mended articular end to the shaft of the bone. The illustrations will give a good idea of the method. (Figs. 9, 10, and 21.)

In the case of the knee and the elbow the joint cavity must be opened, and the fragments reduced so exactly to their relative positions that the joint surface is perfectly restored. In this position they are held and transfixed by a long drill from side to side, and into the hole so made is passed a long bolt which is 3/32 inch or 1/8 inch thick according to the size of the bone. The head of the bolt carries one plate and another plate is passed over its opposite end and secured tightly by a nut, when the projecting end of the bolt is cut off. It is important that the bolt should be made of soft iron so as to make this latter proceeding easy. Then the other ends of the plate are bolted to the shaft of the bone after an accurate reduction of this part of the fracture. The plates are only 1/16 inch thick, and being of soft iron they become bent to fit the contour of the bone. The application of the second bolt so as to pass through the holes ready made for it in the plates must be done by means of a special drill guide. (Fig. 11.)

In the elbow this operation is somewhat difficult because of the close neighbourhood of the ulnar and musculo-spiral nerves, and because there is only one spot where the articular end of the humerus can be transfixed without entering the coronoid or olecranon fossæ. This spot lies just in front of the epicondyles, and to reach it the origin of the extensor muscles with the musculo-spiral nerve must be retracted outwards. In the ends of the femur and tibia which form the knee-joint the method is easy because there are very large surfaces for transfixion, and these surfaces are uncovered by any important structures.

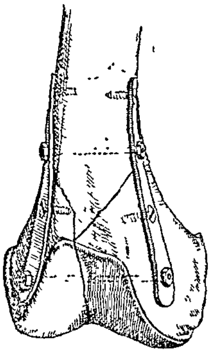
In bad cases of fractures close to the ankle-joint this method is of the greatest utility. It is absolutely essential that the malleolar processes of the tibia and the fibula should not only be accurately replaced, but that they should be so firmly fixed that they will not yield when the pressure of the body weight is put upon them. I show the ankle of a labouring man who was treated by one of the most up-to-date methods of non-operative methods—viz., that of immediate massage with early movements. It will be seen that although the end of the fibula has united very firmly to the shaft, the callus has yielded before the body weight and the socket of the ankle-joint become permanently deformed, so that unless it can be corrected the patient has an extreme talipes valgus which will incapacitate him from his ordinary work for the rest of his life.

FIG. 9.



Fracture of lower end of humerus into joint treated by bolted-plate method.

FIG. 10.



Bolted plate method for fracture of the lower end of the femur.

Such a displacement as this could never have been prevented by any plate and screws which hold only to the outer surface of the broken bone. The bolted plate method, on the other hand, is very easy of application in fractures about the ankle, and I give an illustration of the foot of a woman weighing 18 st., who was able to walk four weeks after the operation, and when seen six months later had a perfectly good anatomical and functional result. (Fig. 21.)

The Bolted Plate Method for the Shafts of the Long Bones.

It is in the bones of the leg, the femur and the tibia, that this method is of the most value, because in this situation we have to aim at a union which is not only firm enough to withstand great muscular strain, but one which is strong enough to bear the weight of the body before the occurrence of full bony union.

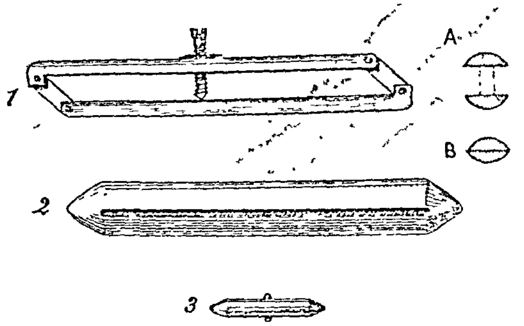
oblivious of the swelling. And again, however the peg is used, it can never hold the bones firmly or rigidly, and a patient can never walk upon a leg so mended until vital repair is complete.

The humerus is the bone above all others where pegging should find its chief use. As I have already noted, it is difficult to make an extensive exposure of the humerus sufficient for good plating without great danger to the soft parts. Pegging can be done through quite a small incision. Further, the humerus is the bone where non-union is most common, and the pegging method with its callus stimulation is well suited to prevent this. I have spent much time and thought in trying to make intramedullary pegs which could be removed after bone union had occurred, and although I have succeeded in this attempt I hardly think the device of much practical value. It consists of a wire spiral coiled in three layers, the inner and outer being circular turns and the middle longitudinal. It can be completely withdrawn from the bone without disturbing the fracture. Its defects are that it has to fit loosely, in order to be readily introduced, and that it is not rigid enough to act as an internal splint.

Another type of intramedullary peg, made both in steel and in ivory, is adjustable, folding in a small space and yet capable of expansion so that it fits tightly in the bone, holding it more rigidly than any solid peg.

The illustration (Fig. 18) shows this to consist really of two plates 3 inches long and 1/8 inch thick, curved on their outer surface to the circumference of a ½ inch circle. These are united by short bars 3/8 inch long at each end, the four pieces being so hinged together that it collapses to the form of a bar ¼ inch thick, or opens to a quadrilateral which forms part of a cylinder ½ inch in diameter. This opening process is effected by means of one screw driven in through the fracture line where it remains, keeping the apparatus in place. When tightened up, this really forms a double internal plate and it holds the fragments beautifully rigid. It by no means fills the marrow cavity, and it fits so loosely when collapsed that, by means of a wire through the screw hole, it can be slipped into the interior of the bone without any boring, and the screw adjustment makes it tightly fit into any bone into which it can be placed.

FIG. 18.



Three types of intramedullary pegs. 1. = Adjustable peg made of metal or ivory. It is inserted closed, the section then being as at B ¼″ × 5/16″. When inside the fracture it is opened by the screw, and when fully open it is part of a cylinder ½″ in diameter as in A. 2. = Long bone peg—full size being 3″ × ½″, with central hole and lateral grooves for insertion by wire traction. 3. = Small peg with fixed cross piece. This should be made of solid ivory and not perforated by a peg, which makes a weak place where most strength is needed.

The Treatment of Old Cases of Non-Union.

There are two measures which may be advocated for this condition. The first is the use of pegs made of solid metallic magnesium, which I have shown has a most stimulating effect on callus production.

The second is the use of a living bone graft. This latter is, of course, no new idea, but I would venture to point out how it may be applied in the way most likely to give success.

For a bone graft to grow in a new place it is very desirable that it should be very closely applied to a large surface of fresh cut bone, and that it should be firmly held there, so as to allow no movement. A graft cut from the front of the tibia cannot be used in the ordinary way as an intramedullary peg because it will not fit the marrow cavity of the bone, and therefore can only be tied there loosely by wire. I believe this is the reason why many of the grafting operations done for non-union have given such poor results.

FIG. 19.

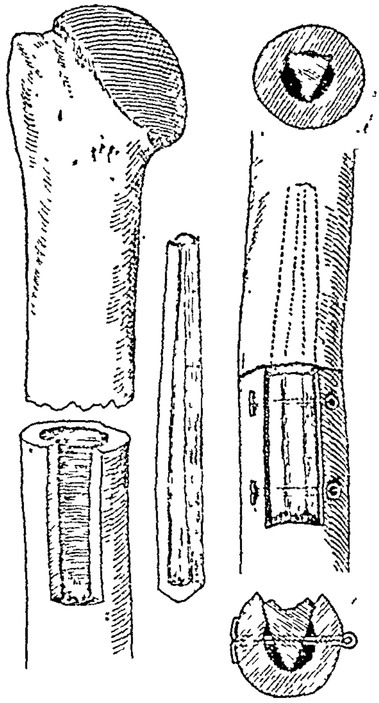


Diagram showing method of treating old ununited fracture by a bone graft from the tibia.

The technique I would suggest is as follows, and it is illustrated in a case of faulty union of the knee-joint 15 years after excision. The graft is cut of good length and substance by a special circular saw from the front of the tibia. It will be roughly square in section. The smaller end is to be pared down so as to fit tightly one end of the broken bone into which it is driven for half its length. The other half of the graft is fitted to the other end of the bone, after removing a sufficient piece from about one-third of its circumference. There it is secured by perforating and encircling wire or by split pins. (Fig. 19.)

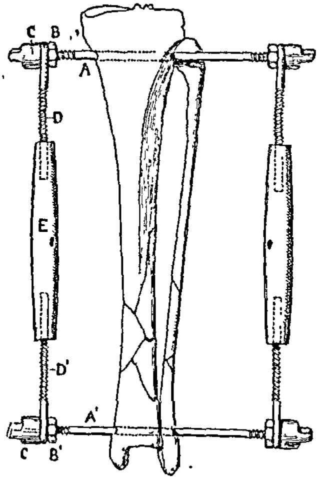
The Method of Indirect Fixation by Transfixion Apparatus.

This method is, as far as my own work is concerned, founded entirely upon, and suggested by, the experiments already described. But since doing these experiments and using the apparatus I have found that Dr. Lambret, of Paris, has invented *practically the same thing.*

I have attempted to apply the method of double transfixion to the humerus, femur, and the forearm, but without any success, and the method, as far as I know it, is only suitable for the leg below the knee. In the thigh it is possible to make an adaptation of the nail extension method of Steinmann and Codivilla by fixing the ends of the nail to steel extension bars which take their purchase from a ring round the groin, and this is useful when patients first begin to move after the nail extension treatment, as it shortens their stay in bed. The double transfixion apparatus is, however, invaluable in certain fractures of the lower leg bones, particularly those which are much comminuted or complicated by a wound or an unhealthy condition of the skin.

The principle of the apparatus is very simple, but the details necessary in its construction and application are important. The illustrations (Figs. 20, 22, and 23) will explain the nature and structure of the apparatus. Take, for example, a comminuted fracture of the lower end of both bones of the leg. The limb is cleaned in the ordinary way, and painted with 10 per cent. iodine from the knee to the toes. Everything is prepared in readiness and the patient is given gas, which must be employed for about five minutes. The two spots for transfixion are chosen and marked on the outside of the leg by short skin incisions. One should be just above the ankle-joint (one inch higher than the tip of the internal malleolus being a safe measurement), and the other opposite the tubercle of the tibia or lower down the leg (in this latter case the transfixion *must go through the front of the tibia to avoid danger of wounding the vessels*). The two transfixion bars, which are provided with bradawl ends and heads which fit a drill handle, are then made to pierce the bones, the lower one usually taking both tibia and fibula, the upper one the tibia only. Whilst this is done the leg must be strongly pulled upon and the fracture adjusted as accurately as possible. It is wise to use a drill guide, by which it is assured that the two pins enter the bone by exactly parallel routes. This is the only part of the operation for which the anæsthetic is necessary, but if it is the case of an excitable person it ought to be prolonged until the outside bars are screwed into place. These consist of rods which can be lengthened by means of a double or reversed screw, and which are fixed on to the transfixing pins by double nuts. The final adjustment of the bone can be made with the aid of the fluorescent screen.

FIG. 20.



Double transfixion apparatus for complicated fractures of the leg bones. A, A′ = highly tempered steel bars which transfix the tibia above and both bones below. They are sufficiently long to act as springs when their ends are pushed apart. One end of each is a drill point and the other is slotted to fit a drill handle, so that each is used to bore its own hole. B, B′ = nuts screwed on to A, A′ after insertion. C, C′ = screw caps which protect the ends of A, A′ and fix the apparatus rigidly when a correct position has been attained. D, D′ = rods with eyes which slip over A, A′ and opposite screw threads which fit into cylinder E.

If the transfixing pins are made of properly tempered steel they will act as a spring which keeps a constant extension as long as the side screws are tight. After a few days the patient can leave his bed and walk with crutches, and at the end of ten days he can put his foot to the ground and gradually bear his weight upon his injured leg. The little wounds on either side of the pins give no trouble, but they should of course be dressed at intervals. The apparatus is removed in three weeks in the comminuted cases when union is rapid, but it may be left on for six weeks in a case where union is slow.

THE CLINICAL PROBLEM: THE CHOICE OF METHOD.

For the practical man who wants to do the best for his patient, it is of the utmost importance to know what methods are available for the treatment of fractures and how they may be chosen for suitable cases. It is not so much a question as to whether method A, B, or C gives the best results if applied to all cases, but rather what are the special merits of each method which make them suitable for any special case.

The non-operative methods of fracture treatment fall into three groups—(1) immobilisation by splints and plaster; (2) massage with mobilisation; and (3) extension. Practically these three types of treatment represent principles two or three of which can often be applied for the treatment of the same case. But inasmuch as the massage and the extension methods are often spoken of as though they were self-contained and independent systems, it may be well to examine the chief possibilities and limitations of each of these methods.

Immobilisation by Splints or Plaster.

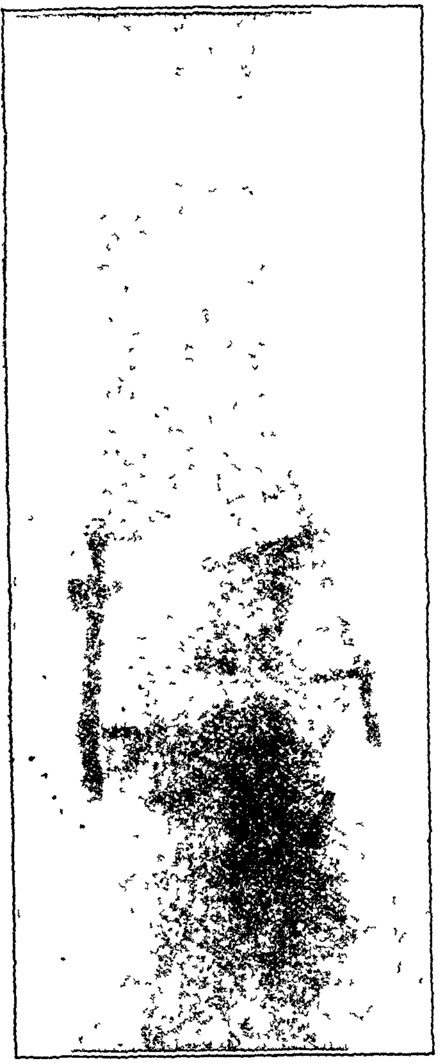
This is the old method, going back to prehistoric times. *It is almost everything that is bad. It does* nothing to reduce the deformity, it allows enough movement between the fragments to cause great callus excess, it keeps the patient in bed or inactive for the longest possible time, it does everything that can be done to make the muscles waste, the tendons adhere to their sheaths, and the joints to become fixed. And it conceals the prospect of all these evil results beneath the covering of elegant bandaging, so that they are not apparent until too late for remedy.

One good feature the method has, which unfortunately, with many, outweighs all its evils. It is easy both for patient and practitioner at the time. Perhaps one half hour is given to fixing the arm on an angular splint or to putting the leg into plaster, and then nothing more has to be done for a month or two, except for the patient to enjoy his convalescence and the surgeon to come and chat to him about the weather from time to time. Hence it is that the method which goes back to the Pharaohs seems likely to flourish for many a generation to come, so long in fact as "Laissez faire," "Solvitur ambulando," and "Wait and see" are the most popular mottoes of the day.

There may be some who read these words and think them a gross exaggeration, for they say that many a case has done well by the splint and plaster treatment. This is quite true, and it is this that makes the whole difficulty. If every case treated by a splint became maimed or lame for life no argument would be needed to condemn the method. Possibly the majority of the patients treated by it get a finally good result. But this good result is not because of the treatment, but rather in spite of it—that is to say, splint treatment is not treatment at all, except in a negative sense of the word. It is treatment only in the sense that bed is the treatment for enteric fever. Every broken bone, the fragments of which are not much displaced, will, if protected from further injury, heal. But when the fragments are displaced, the splint or plaster will do nothing to restore the proper form to the bone, and they also increase the functional loss due to adhesion of muscles and joints.

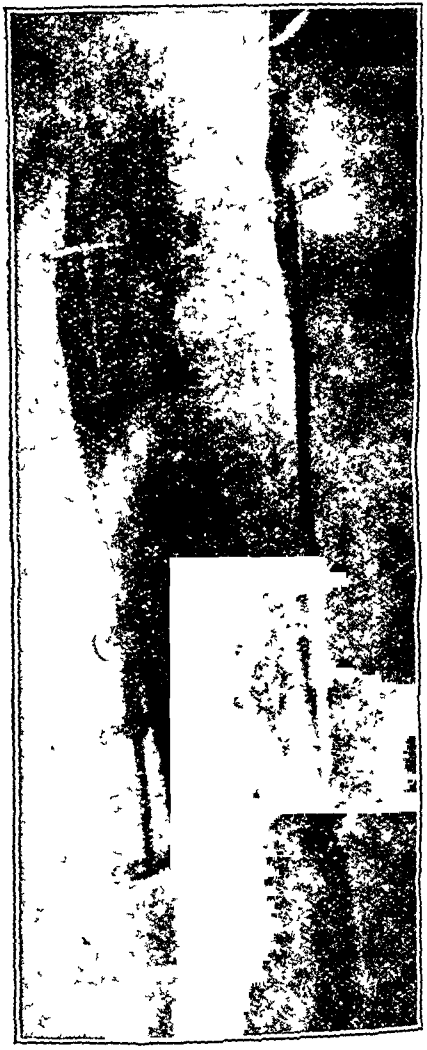
The only fractures that do well with the splint treatment are those in which the displacement of the fragments is trivial, and in such cases prolonged splinting is quite unnecessary, except in the form of a movable splint, only to be used during exercise and taken off when in bed and for massage.

FIG. 21



Skiagram of the ankle of a woman who weighed 18 st., with a double malleolar fracture Operation, June, 1913 Could put the foot to the ground three weeks later. Last seen December, 1913. The function was good.

FIG. 22.



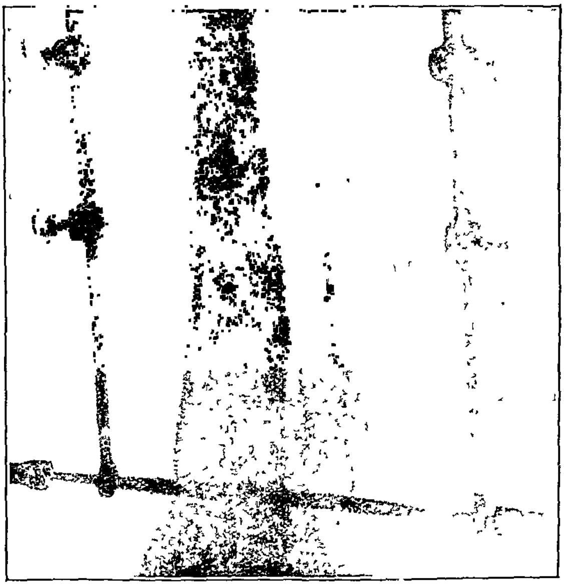
Photograph of man's leg one week after the application of the double transfixion apparatus for a severely comminuted fracture above the ankle.

The fixing of a limb on a splint which immobilises the joint above and below the fracture, and which is not removed for weeks together, ought to be abandoned absolutely, unless under exceptional circumstances (e.g., lunatics, those who are at sea, or a patient suffering from delirium). Such treatment is either too much or too little. It is too much for a subperiosteal fracture without displacement, and it is too little for a complete fracture with displacement.

The Method of Massage and Early Movement.

This as the sole method of treating all fractures I know nothing about. To my mind it is an important concomitant to other methods of treatment rather than a method standing by itself. About its value in those cases where there is but slight displacement there can be no doubt. It soothes pain, relaxes muscle spasm, and prevents both œdema and adhesions. It is its applicability to cases with much displacement which appears so doubtful. It is said that the light stroking massage, by which the limb is soothed, as it were, into a hypnotic trance, actually relaxes the muscles so much that the displaced bones can [illegible] relaxation lasts not for [illegible] of an anæsthetic but fc [illegible] massage séances a day, the limb may be kept in proper position even with a complete and easily *displaced fracture. This statement has been made,* and its truth witnessed by so many careful observers that it would seem to be folly to doubt it, and yet there seems to be about it a flavour of romance which does not appeal to the practical surgeon.

FIG. 23



Sklagram of the same patient as in Fig 22 The apparatus was removed after three weeks, and he returned to work in six weeks.

There are three points about the method as applicable to bad fractures, which compel me to think that it will not be widely used. In the first place, it was never adopted at all widely in Paris, in spite of the enthusiastic advocacy of the late Professor Lucas-Championnière, and in that city the method is now but little used. Then it requires someone with a very special skill and experience to carry it out, and if this be the surgeon he must be prepared to devote about one hour a day to each case for some weeks. And, lastly, there has always been a reluctance on the part of the extreme advocates of the method to put forward X ray evidence that fractures with gross deformity can be treated by it in such a way that the deformity is reduced. This engenders a suspicion either that there are no cures of deformity to show or else that the deformities often go uncured. However, in cases without much displacement the method is invaluable both for the sake of expediting recovery and securing a perfect functional result. If used with a minimum of fixation apparatus which is taken off twice a day, it should replace the old immobilisation on splints for all the lesser degrees of fracture.

The Methods of Extension.

The method which has been applied with all the thoroughness of the Teutonic genius to the greatest number and variety of fractures with the best results is that of the late Professor Bardenheuer, of Cologne. No one else has ever produced such good results, or if so, such results have never been made public. But [illegible] 100 hospital beds, a large [illegible] d a nursing sisterhood all [illegible] ject, and even in Germany it has been found that the method is often difficult and unsatisfactory from a practical point of view. However, it has been proved beyond all doubt that the principle of extension, if efficiently applied, is capable of giving good results in all the regular fractures.

It is when it is sought to extend its scope to the *treatment of complicated fractures, so that the* simple longitudinal pull has to be reinforced by several lateral or rotatory pulls, that the method becomes difficult of application, and likely to give poor results at the cost of much delay in the hands of any but the most experienced. Codivilla and Steinmann have rendered very good service in showing that by transfixing the bones by a nail such powerful direct traction can be made on the bone by the nail that the extension principle will produce much greater and quicker results. This is of especial value in the femur of adults, where there is great muscular tension to be overcome.

By whatever method extension is applied, it will produce its full effect in relaxing the muscles and reducing displacement within a few days. Then the fracture ought to be re examined by the X rays, and upon the result of this examination, depends the answer to the question of the need of operation in most cases. It cannot be too strongly insisted that the X ray examination of the fracture is not only the essential and most important *point of the diagnosis*, but that no method of treatment should be persisted in unless the X rays have proved that it has reduced the fragments to a good position. At the present day most of the really bad fracture results arise in cases which have been tied up in a splint for one or two months, and no X ray picture has been taken until obvious deformity and disability are demonstrated by other evidence.

There are two important cautions required in accepting an X ray verdict as to the good position of a fracture. The first, which has often been mentioned, is that the picture should be taken from different directions. The reason for this is so obvious and has so often been demonstrated, that there is no need to dwell upon it. But the other is one not so generally recognised. It is that the good position of the bone at one period of extension may be quite lost later on when the soft callus yields to the traction of the muscles or to the weight of the body.

This applies especially to oblique fractures of the shaft of the femur in adults, and I show two examples. In each of these the fragments had been brought into good position by extension, but several weeks later the bone had again slipped, so that there was much over-lapping.

I am showing to-day, and leaving for your inspection, a number of skiagrams of mal-united fractures. These cases have all been seen for insurance companies in the course of the last two years. They have all been treated in large hospitals by approved non-operative methods, and in all of them there has resulted permanent total incapacity for work, in the legal sense of the term. This, I think, affords evidence, if such is needed, of the necessity of the adoption of better methods of treating fractures, not so much by the country doctor, as by the hospital surgeon, to whom he sends his cases.

The Cases for Operative Treatment.

Most surgeons are agreed that fractures without displacement are to be treated by massage and movement and intermittent retentive apparatus; that cases with displacement must have immediate extension applied, and that if this fails to give a good reduction, operation is to be undertaken. But the matter cannot be concluded so simply as this. For, on the one hand, there are some cases in which, in spite of considerable persistence of displacement, a good result may be looked for eventually: whereas in other cases, though the displacement can be reduced by the apparatus and extension, there is a probability that it will quickly recur, or that it will yield before the body weight or that firm union will occupy a very long period under a non-operative *régime.*

In general terms it may be said that the following groups represent the factors which will determine in most cases whether an operative or non-operative method should be employed:—

Factors which make for success of non-operative methods:—

Youth of patient—i.e., during active bone growth; until puberty there is great capacity for bone repair and restoration of form and function.

Subperiosteal or partial fracture.

Fractures with little or no displacement.

Fractures of one only of the paired bones of the forearm or lower leg, especially of the ulna or fibula.

The majority of arm fractures.

Factors which indicate advisability of operation:—

Adult age. In fully grown bones, especially those of old people, there is good capacity for repair, but little for restitution of mal-union.

Fractures with gross displacement, especially oblique and spiral fractures.

Fractures of the shafts of the femur and of both tibia and fibula.

Fractures into or near the elbow, knee, and ankle.

Of course, there will always be a certain group of cases about which surgeons will disagree. A man will advise non-operative or operative treatment in such cases according as he has skill, confidence, and experience in a particular method. And further there will always be some cases about which a broad-minded surgeon will be in doubt, and such cases can only be decided on their own merits and not according to any general law.

There is a week in which to make this decision, and it is well to avoid either extreme of deciding on operation too quickly or postponing it too long. If anatomical restitution of form is to be the chief guide it is unreasonable to act upon a skiagram taken before extension was applied, and it is foolish to wait until a mal-union has occurred between the bones. It is quite certain that no fair judgment can be made in this matter by any but one who has mastered both the non-operative and the operative treatment of fractures. The enthusiast for bloodless surgery will be liable to wait far too long trying his manipulations in some hopeless case of displacement; whilst the enthusiast for operations will give no time for a reasonable attempt at non-operative reduction in many a case which would have yielded quite simply to this treatment. I wish to make it quite clear that I am not advocating the treatment of all cases by non-operative means, reserving the operation for those in which the former has failed, but simply that in the doubtful cases one week's trial of really efficient extension should be given and its results judged by the X rays before operation be decided on.

Comparison of Non-operative and Operative Treatment of Fractures.

In the broad sense of the word it would seem to me to be absurd and useless to institute a "comparison" between the results of non-operative and operative methods of treating fractures. And yet one often hears the question asked, "Do you believe in operating upon fractures?" As well might one ask, "Do you believe in drugs?" or institute a comparison between the non-operative and operative treatment of dyspepsia. Personally, I have very little doubt that if the system of treating every case of dyspepsia by operation were to be compared with that of treating all such cases without operation the results of the former would be very much better than the latter. But both plans would be criminal. Similarly, to inquire whether the non-operative or operative methods of treating fractures give the better result, is to assume that there exists a responsible surgeon who would suggest that no fracture should be submitted to operation on the one hand, or another who says that every fracture should be dealt with by the knife. The most conservative surgeon would not allow a fractured patella with much displacement to go unsutured, nor would the most ardent advocate of operations suggest an open attack upon a subperiosteal fracture of the fibula without displacement. Therefore, the main problem must ever be, not non-operative *versus* operative methods, but rather the selection of those cases suitable for the one method or the other.

However, the comparison between the two groups of methods has recently been seriously undertaken by a committee of the Surgical Section of the British Medical Association, and they have, in spite of the illogical and impossible nature of their task, produced one of the most valuable contributions to the literature of fractures that has ever appeared. They have examined over 2900 cases, and not only recorded the remote results in all of these, but they have so carefully arranged and analysed their figures, that their results form a mine of information and an authoritative standard by which all subsequent fracture work can be measured, and with which it can be compared. They themselves admit that, "It is undesirable to attempt to draw any final conclusions from this material as to the relative value of operative or non-operative treatment." Taking all cases together, the non-operative methods show 70·4 per cent. good functional results, whilst the operative claim 79·1 per cent. On the other hand, the non-operative produces 11·8 per cent. really bad results, and the operative 9·5 per cent. So that on this basis, which is that which shows the operative method in its least favourable light, there is this much to be claimed, that operative methods get 9 per cent. more good results and 2 per cent. fewer bad results than the non-operative. If the cases are divided into age groups, and only those considered above 15, then the results of operative are 21 per cent. better than those of non-operative methods.

Such figures will be regarded very differently by different observers. If there are any who think that all fractures could be treated by the one class of method or the other, then to such it will appear very doubtful whether only 9 per cent. better results for operative methods is justification for submitting 81 per cent. of patients to operation, who would have done just as well without it. But to the surgeon who thinks that operations should be reserved for the more complicated types of fractures, such figures would provide both encouragement and stimulus, for they would show that operations can produce better results in complicated cases, than the conservative methods do in the simplest.

The fact that out of a total of 2904 cases 2596 were non-operative and 308 operative is pretty clear evidence that at the period of observation, as only 1 out of every 10 cases was operated upon, these presumably were the most difficult and unpromising types. But without some knowledge of how cases were selected for operation, the figures can afford us no basis of comparison.

The great and lasting value of the fracture committee's report consists in the careful analysis of the anatomical and functional results of the large number of the non-operative cases they examined. Of the most fundamental importance is their demonstration of the dependence of good function upon perfect anatomical restoration. Good form secures good function in 90 per cent. of cases whereas moderate or bad restoration of form leads to bad function in 70 per cent.

It is particularly interesting to notice in which groups of cases the non-operative methods have given a high proportion of bad results, because this must give us a very significant indication as to the direction in which our operative activities may usefully be turned in the future. I have selected those cases only of patients over 15 years, because in general terms there is but little scope for operative treatment in any of the closed fractures of children.

Region of fracture.	Number of cases above 15 years.	Cases with good functional result.	
		Number.	Percentage.
Neck of femur	87	24	27
Upper third of femur	49	23	47
Lower end of femur	10	4	40
Tibia and fibula (simultaneous) ...	432	275	64
Pott's fracture	238	111	47
Supracondylic fracture of humerus	11	4	36

It is quite clear that there is great scope for improvement in all these groups, and I am certain that a proper operative technique could bring about this improvement in most cases. It will be noticed that five out of six of these groups are those in the operative treatment of which, I have urged already, on other grounds, the necessity of some special methods of fixation which attain the ideals of mechanical efficiency so necessary for success. The first group—that of fractures of the neck of the femur—presents a most difficult problem, which I do not feel at present justified in discussing. If we ask to what extent operators have attempted to deal with these groups of fractures we find clear evidence that these very cases, in which there is so much need for improved methods, surgeons have done but little. Of primary operations on adults there have only been the following:—

Neck of femur	0	Tibia and fibula	20
Upper third of femur	0	Pott's fracture	4
Lower end of femur	1	Humerus, supracondylic ...	0

And of these the only group containing enough cases to consider the proportion of successes—viz., that of the simultaneous fracture of the shafts of the tibia and fibula—the good functional results have only been 13 out of 20, i.e., 65 per cent.

The following inferences from these figures seem to be justified. 1. In these groups of cases there is greatly needed an improved method of treating adult fractures. 2. There is not any generally accepted method of operative treatment to meet this difficulty in any of these groups, with the exception of fractures of the shafts of the tibia and fibula. 3. At the date of the report it was in that group of cases which gives the best results to non-operative methods (tibia and fibula) that there has been the greatest activity in operating, whereas in those groups where there has been the greatest failure of the old methods the new surgery has done almost nothing. 4. Even in the one class where most operating has been done (tibias and fibulas) the results are only 1 per cent. better than those obtained by conservatism.

I think all these deductions from the report of the fracture committee point very strongly both to the need of the more frequent employment of operative treatment in certain groups of fracture, and also to the necessity of improving our operative methods. Progress in the treatment of fractures can only take place when all methods are mastered and applied with discrimination to suitable cases. There are two things necessary for a general improvement of our results. The first is that anatomically accurate reposition of the fragments, as demonstrated by the X rays, should be the standard by which the treatment of each case must be judged. The *laissez faire*, or "wait-and-see" policy of tying a limb to a stick and trusting to luck must be replaced by an accurate method of treatment, which only leaves the limb to nature if and when the bones are in good position. The second is that when we do operate we must employ a method which is mechanically efficient not only to bring the bones together but to hold them there firmly, whilst early movement is carried out and until solid union has occurred.

The ideals which I set before myself in the operative treatment of fractures are: 1. Not to operate upon any case which would probably give as good a result by conservative treatment. 2. To employ a method which will ensure perfect anatomical restoration of form. 3. To secure such efficiency of mechanical fixation that at the conclusion of the operation the bone is stronger than before the fracture. 4. To do this by a method of fixation which will last for an indefinite time, and does not depend upon the frictional grip of nails and screws upon the bone. 5. To restore the limb to a condition in which it can be freely moved as soon as the skin wound has healed—i.e., in 7 to 14 days, and used for its full natural function in a period of 3 weeks to 3 months according to the bone involved. I am keenly alive to the fact that at present these ideals have not been fully attained, but I believe that there is nothing impossible in their attainment, and whilst these ideals remain unfulfilled, they provide both stimulus and goal for future work.

THE THYREOGLOSSAL TRACT.*

By W. G. SPENCER, M.S. Lond., F.R.C.S. Eng.,

SURGEON TO THE WESTMINSTER HOSPITAL.

In the treatment by operation of the abnormalities which occur in the course of the thyreoglossal tract there is a tendency to excess on the one hand, by which essential thyroid gland tissue is removed under the mistaken idea that a new growth must be taken away, with the result that operative myxœdema, cachexia strumipriva, has followed; on the other hand, owing to limited operations on cysts, a sinus opening upon the neck is set up which persists, or is only cured after several operations.

The observations which have been made upon the development of the thyroid gland subsequent to the description given by His have shown that the thyroid gland is chiefly developed from the median thyroid rudiment.[1] This rudiment, in the human embryo during the third week, grows out below the floor of the primitive mouth in intimate relation to the developing hyoid bone. As the neck of the embryo elongates, it is carried backwards as a pedunculated mass. Then the enlarged end becomes bilobed and forms the isthmus and major part of the lateral lobes of the normal thyroid gland, whilst the pedicle under normal conditions to a large extent disappears or portions become constricted off and isolated in the line from the pyramidal lobe to the foramen cæcum.

Persistence of thyroid gland tissue in the course of the thyreoglossal tract stands in an inverse relation to the normal development of the thyroid gland. In vertebrates below mammals the median thyroid rudiment is the only source of thyroid gland tissue as distinguished by alveoli containing colloid. The dog-fish has simply a median thyroid which is continued forwards through the hyoid cartilage to end beneath the skin of the tongue. But in higher forms behind the last branchial pouches, or from a freely developed fifth branchial pouch, there arises a pair of outgrowths, the ultimo-branchial (post-branchial, teleobranchial) bodies, which in mammals take some share in the formation of the lateral lobes of the thyroid gland.[2] Below mammals these ultimo-branchial bodies, although of an epithelial structure, do not exhibit follicles containing colloid. In echidna the lateral thyroid masses contain colloid but do not unite with the median thyroid process. In higher mammals this union occurs whenever normal thyroid gland is developed, but none the less the median thyroid rudiment has the largest share in its formation. Under normal conditions some thyroid gland alveoli containing colloid are generally found in the position of the pyramidal lobe. Also, but not so generally, as first discovered by Verneuil,[3] particles of thyroid gland tissue may be found at the root of the tongue.

From the clinical standpoint, however, no thyroid gland masses are noticeable in the course of the thyreoglossal tract under normal conditions; and, on the other hand, whenever such masses are met with the presumption should be that they are compensatory to some arrest in the development of the normal thyroid gland. More important still, when no proper thyroid gland is developed in the neck, then all the actively functional thyroid gland tissue is placed in the line of the thyreoglossal tract. If this suffices for the patient's needs the absence of the thyroid gland from its proper position passes unnoticed. When about puberty, especially in females, the thyroid gland tissue becomes temporarily more active and vascular, it is then that the existence of a mass at the base of the tongue, or about the hyoid bone in the neck, may present itself. Far from being a new growth or of recent formation, this ought to be considered a temporary parenchymatous enlargement of the patient's real thyroid gland, although it is not in the usual situation.

The median thyroid process in developing below the floor of the primitive mouth does so around a median ventral epithelial pouch. In the amphioxus this pouch is formed without any thyroid gland tissue around and, according to Wiedersheim, secretes mucus which sticks together entering food particles and so prevents them from being washed out again through the gills. In higher forms the epithelial sinus develops in the middle of the median thyroid rudiment, but the thyroid gland tissue always consists of closed alveoli containing colloid which do not open at any stage into the epithelial sinus. The glands which are formed by outgrowths from the epithelial sinus are similar to buccal glands; therefore this epithelial sinus is at no stage a duct of a thyroid gland. In man it forms the foramen cæcum, a blind pouch about 1 cm. deep into which open the mucous glands, to which it therefore forms a short common duct, and only in this limited sense can it be called the "lingual duct." Kanthack,[4] examining 100 adult cadavers, found the foramen cæcum absent in many cases and never any long sinus: the longest canal in a new-born child measured 5 cm. This epithelial sinus was called the "lingual duct" by Vater,[5] who by a forced injection made out a connexion between the foramen cæcum and the thyroid gland, a mistake repeated by others since Vater's time.

Whilst the normal condition in man is for a sinus lined by stratified epithelium to extend from the foramen cæcum a few millimetres backwards under the surface epithelium, and into which mucous glands open, it is subject to abnormalities of two kinds, a prolongation in the line of the median thyroid process, and a lateral branching. These persisting extensions may be lined either by squamous or by ciliated columnar epithelium, indicating that the sinus is developed at the junction of the primitive mouth with its covering of squamous epithelium and of the primitive pharynx lined by ciliated epithelium. But neither the squamous epithelium nor the ciliated columnar epithelium has any essential connexion with the thyroid gland.

When the prolongation of this epithelial sinus in the line of the median thyroid process is cut off from its connexion with the foramen cæcum, there is developed a cyst, which is usually seen in the neck just below the hyoid bone, less commonly underneath the position of the foramen cæcum. Therefore, although the median thyroid process is developed around this epithelial sinus, the two should be regarded as having no physiological connexion. Stillborn and non-viable myxœdematous infants such as are not uncommon in goitrous districts may present no development of thyroid tissue at all. The epithelial sinus and its outgrowths then exist alone. Thus in the case of a female child aged 3 months, 50 cm. in length and markedly myxœdematous, there was a complete absence of the thyroid gland, but in the position of the foramen cæcum an irregular epithelial cystic mass (Dieterlé[6]). Among a collection of 25, eight such cases were described by Ungermann.[7]

---

* A paper read at a meeting of the Surgical Section of the Royal Society of Medicine on Feb. 10th, 1914.

In a myxœdematous infant a small, although insufficient, mass of thyroid tissue may be found. Thus a myxœdematous infant aged 6 months, 53 cm. in length, with short thick extremities, was noted post mortem to have no sign of a normal thyroid; there was an enlargement of the pituitary body and at the base of the tongue a cyst of the size of a pea with some thyroid gland follicles containing colloid in its wall (Ashoff[8]). Even if lateral thyroid or parathyroid masses exist in the neck, yet, if there has been a deficiency in the development of the median thyroid rudiment, myxœdema results. Hence, if on clinical examination no isthmus can be felt in front of the trachea, gland-like swellings alongside the trachea should be considered parathyroid, and not assumed to be true functional thyroid gland tissue.

Thus in a boy aged 3 months, 46 cm. long and markedly myxœdematous, along with a complete absence of the normal thyroid gland, there was found an epithelial cystic tumour at the base of the tongue, and in the neck on either side of the trachea four normal and eight accessory parathyroids. In the case of a girl aged 8 months with marked myxœdema there was an absence of a normal thyroid gland. At the foramen cæcum there was a sinus with branching tubes ending in *an epithelial cyst, and around this a very little* thyroid gland tissue. In the neck on either side of the trachea were altogether eight parathyroid masses (Erdheim[9]).

There may, however, be sufficient thyroid gland tissue developed at the base of the tongue. Thus, a *man aged 30 died after excision of the lip for* tuberculous disease. During life there had been no sign of any thyroid insufficiency nor of any swelling at the base of the tongue. Post mortem there was found lying under the foramen cæcum a mass of thyroid gland tissue the size of a chestnut, the alveoli containing colloid. There was no sign of a normal thyroid gland, but by the side of the trachea below the thyroid cartilage were on the right side two masses and on the left one, the size of peas, embedded in fatty and fibrous tissue. On microscopic examination these masses were found to resemble in structure the normal thyroid gland, but the alveoli did not contain colloid. The lingual mass had therefore been the only actively secreting thyroid gland, and the bodies beside his trachea were probably destitute of any such function (Ungermann).

From the standpoint of a clinical examination, then, it is of primary importance to recognise the presence of the isthmus of the thyroid gland or the reverse. When the isthmus is absent so that the tracheal rings from the cricoid cartilage downwards can be felt it should be assumed that the patient's actively secreting thyroid may have been developed in the course of the thyreoglossal tract, and although there may be a fulness on either side of the trachea suggesting the existence of lateral lobes, yet these may be parathyroids destitute of any true thyroid function.

This precaution has been ignored and cases of operative myxœdema following the removal of thyroid gland tissue in the course of the thyreoglossal tract have frequently occurred, and it has been estimated in a district where disease of the thyroid is frequent that it occurs in 1 out of 7 cases (W. H. Mayo[10]). But it is the individual cases which have to be carefully examined before deciding whether there are sufficient indications for the operation. A large number of the recorded cases show that lingual thyroids have been removed without taking note as to the proper development of the thyroid gland, and when they have been reported directly after the operation without waiting to see the result it is much to be feared that in some of the cases myxœdema supervened later. At any rate, there are a number of cases recorded in which myxœdema did subsequently arise and a review of them sufficiently explains the reason of its occurrence.

A tumour was removed from the base of the tongue of a girl, aged 14, after it had been noted for some months. It consisted of thyroid gland tissue with the alveoli containing colloid. A normal thyroid gland could not be felt. Some time later the patient died with symptoms of cachexia strumipriva (Seldowitsch[11]).

A cretin, aged 37, had a tumour the size of a walnut at the base of the tongue. When performing tracheotomy preliminary to excision no normal thyroid gland could be made out. The tumour removed showed thyroid gland tissue, partly normal, partly embryonic. The patient returned five months later suffering from cachexia strumipriva (v. Chamisso[12]).

A girl, aged 20, had no isthmus nor left lateral lobe, but there was a fulness supposed to indicate a *right lateral lobe. A tumour the size of half a nut,* consisting of thyroid gland tissue, was removed from the base of the tongue. Five months later a letter from the patient reported signs of myxœdema (Meixner[13]).

At the age of 7 a girl was noted to have an elastic *swelling the size of a marble in the middle line of* the neck at the level of the thyroid cartilage. It was removed and found to consist of thyroid gland tissue. Three weeks after the operation she began to show signs of myxœdema and continued under active medical treatment for ten years by thyroid extract, but remained at the time of the report in a state of chronic myxœdema (Morley Fletcher[14]).

On the other hand, many cases of lingual thyroid have been seen where the thyroid gland has been noted as absent, and then no operation of removal has been done. Since the two cases recorded by Butlin,[15] one of which afterwards showed signs of myxœdema, I have recognised the functional importance of a lingual thyroid. In three recent cases, all very similar, of girls about 20, with an absence of a thyroid isthmus and a swelling characteristic of a lingual thyroid at the base of the tongue, advice had been previously given that the swelling should be removed, whereas, on the other hand, I advised against any such procedure. I have lost sight of the first two; in a third case she had been to a throat hospital and given a card of admission for operation. I gave her a certificate stating that myxœdema would result if the swelling were removed. All three were suffering from a temporary vascular hypertrophy of the only thyroid gland they possessed. Painting with iodine, the administration of iodide of potassium, perhaps a careful exposure to X rays, should be the treatment.

Where the swelling at the base of the tongue has become so prominent as to impair the breathing or has ulcerated and hæmorrhage has followed, then the removal of a small wedge and suture, or a limited application of the cautery is all that is indicated. An extensive submaxillary operation may not only be excessive but, when a normal thyroid gland is absent, a serious blunder. Fortunately some of the extensive removals have been probably incomplete in spite of the statements of the operators that they had shelled out the tumours. These thyroid masses at the base of the tongue are not circumscribed, but have branches or semi-detached portions so that the patients have been saved from myxœdema in spite of the objective of the surgeon. Hickman[16] described an extreme case of the kind forming a tumour extending from the circumvallate papillæ to the epiglottis and deep into the tongue which caused the death of the infant 16 hours after birth.

Turning to patients possessing a normal thyroid gland it is from the median thyroid rudiment that accessory thyroids so-called arise. The explanation is that they are lateral buds from this tract which are displaced as the embryo grows. Thus they may be found in the floor of the mouth above the mylohyoid to one side or the other. The position of such accessory thyroids corresponds with that of the frog's thyroid gland, in which there is a mass on each side at the tip of the lesser cornu of the hyoid bone, dorsal to the sternohyoid muscles.

In Paton's[17] case an accessory thyroid mass about the size of a walnut was situated underneath the right sublingual salivary gland, which he removed from under the jaw. I removed from the same situation the tumour[18] exhibited which measures 2½ by 1½ by 1 inches; a male child, aged 3 weeks, was suffering from dyspnœa, it had apparently a normal thyroid gland, and I saw it some time after healing in good health. The tumour has the usual naked-eye and microscopic appearances of a fibrocystic thyroid adenoma, and in addition there are islands of hyalin cartilage which came from the region of the cornu of the hyoid bone.

A review of the cases where there has been an accessory thyroid to one or the other side of the true line of the thyreoglossal tract shows that where the normal thyroid gland has been developed their removal is sufficiently indicated; it is when the swelling is situated in the middle line that it may represent the true thyroid gland.

When there is a question in a doubtful case as to the necessity for operation, then it will be generally wise to treat the case expectantly. The only case which tended to become malignant that I can find recorded is the following. A woman, aged 42, with an apparently quite normal thyroid, had had a small tumour removed from the base of the tongue nine years before, when it was stated that not all had been removed. Two years later some enlarged glands were excised from the right submaxillary region; later there was a recurrence of the growth at the root of the tongue and in the right submaxillary region, and in addition an enlargement of the glands on the left side of the neck. At the first operation a mass of glands the size of the doubled fist was removed from the left side of the neck; at the second operation two enlarged glands the size of hazel nuts were removed from the right side, and a nodule the size of a small walnut from the base of the tongue. All showed thyroid gland tissue. The patient was exhibited six months later in good health without recurrence (Brentano[19]).

Thyreoglossal cyst.—The thyreoglossal cyst is generally situated in the neck, protruding just below the hyoid bone, forming whilst small a tense swelling as distinguished from a soft vascular thyroid tumour. It is, as explained above, the blind end of an epithelial sinus which has no functional importance. The cyst lies beneath the median raphe and the adjacent margins of the sternohyoid muscles; it is quite free from any connexion with the thyrohyoid membrane, but at the upper part of the cyst it is closely attached to the hyoid bone. If punctured it continues to discharge mucus, especially during deglutition; this mucus is derived from the mucous glands opening into the sinus especially near the foramen cæcum and from degeneration of the epithelium, but has no relation to thyroid secretion.

If the hyoid bone is hooked upwards, it may be possible to remove the cyst completely from behind the hyoid bone. But when the cyst extends up to the foramen cæcum and is of long standing, it has proved impossible to remove the whole of the cyst without dividing the hyoid bone.

I have thus divided the hyoid bone in the middle line when operating for the first time; but more especially when a fistula has persisted after a previously incomplete operation is this step necessary. In one case the patient had been operated upon elsewhere three times, in another case eight times before coming under my care. The excision of the cyst together with half an inch of the middle of the body of the hyoid bone was followed in both by permanent healing; the division of the hyoid bone is not followed by any disability. The latter case was exhibited at a meeting of the Clinical Section of the Royal Society of Medicine in May, 1913.[20]

In conclusion, I wish to express my thanks to the Royal College of Surgeons of England for permission to exhibit eight specimens from their museum.

Portland-place, W.

PRIMARY CARCINOMA OF THE FIRST PART OF THE DUODENUM WITH SECONDARY INVOLVEMENT OF THE COMMON BILE-DUCT

BY J. P. BIBBY, M.B., CH.B. LEEDS,
RESIDENT MEDICAL OFFICER, GENERAL INFIRMARY, LEEDS,
AND
M. J. STEWART, M.B., CH.B. GLASG., M.R.C.P. LOND.,
CLINICAL PATHOLOGIST, GENERAL INFIRMARY, LEEDS

PRIMARY carcinoma of the duodenum is a rare disease. Its actual frequency, as estimated by Brill[1] from the post mortem records of Maydl, Nothnagel, Muller, and Lubarsch, is 0·3 per cent. of all cases of carcinoma (15 cases in 4675 deaths from carcinoma). In a majority of the recorded cases the disease has involved the second part of the duodenum, and in not a few of these the opening of the common bile duct has been implicated. The case here recorded appears to be unique in that a carcinoma arising primarily in the first part has, by direct extension, come to involve the common bile duct in the middle of its course, leading finally to a clinical picture in which the outstanding phenomena were those of obstruction in this latter situation.

On July 14th, 1913, a man, aged 61, was admitted to the wards of the General Infirmary at Leeds, under the care of Dr. A. G. Barrs. The appearance of the patient was striking. He was deeply jaundiced, the jaundice being remarkable for its ruddiness. He was feeble, wasted, and lethargic, obviously suffering from a dire disease. His complaints were three—yellowness of the skin, abdominal discomfort, and hiccough. The history obtained was marked by its brevity and was barren of assistance in accurate localisation of the primary condition. Three months seemed to cover the time that he was sensible of change in himself. For that period he had been troubled with indigestion of the flatulent variety, discomfort being almost continuous, though occasionally he was disturbed by paroxysms of pain coming on half an hour after food. Water brash was not infrequent, whilst less often he vomited a trifling amount of what he called "darkish coloured fluid." From the outset he had lost weight steadily, though more rapidly latterly. A month ago he noticed his urine getting darker, his motions paler, and then his skin became yellow, deepening rapidly in hue, and without remission. His past personal history revealed little, and for the last 12 years he had apparently been rigidly temperate in all things. His wife, however, told us that three years ago he had suffered from an attack of somewhat severe abdominal pain, localised to the upper part of the abdomen, not specially to one side, colicky in nature, unaccompanied by jaundice, and he had not passed anything abnormal by the rectum.

On admission the temperature was 100° F., but rapidly fell to normal, and remained so until the end. The pulse was 80 per minute, regular, though feeble. Frequent hiccough disturbed the patient and the examination. The abdomen was hollow, the skin of the lower part striated, and there was no distension of veins. There was some slight tenderness in the right hypochondrium, clinically *the liver was neither enlarged nor diminished*. The gall bladder was not palpable, nor were there signs of fluid in the peritoneal cavity. The stomach was not dilated, and peristaltic action of this organ or of the intestines was not seen. Rectal examination was negative. Examination of the urine revealed the presence of bile, some albumin, and numerous granular and epithelial casts. Leucin and tyrosin were not found. Neither the fæces nor the urine gave evidence of pancreatic insufficiency.

A diagnosis of "obstruction of the common bile duct by malignant disease" was made, there being insufficient evidence to implicate any organ as the primary seat. Dr. Barrs hesitated in making a diagnosis of either primary disease in the duct itself or of the duodenum. From the moment of admission the patient rapidly got worse, and the illness ended fatally four days later, on July 18th.

Post mortem examination.—External appearances. The integuments and conjunctivæ were stained an intense golden yellow colour. The little toes were markedly dorsiflexed and adducted, so that they came to overlap the next digit in each instance.

Internal examination. On laying open the intestine a tumour was found in the first part of the duodenum, commencing 1½ inches from the pylorus and extending along the gut for a distance of about 2 inches. The growth was 3 inches in length, and almost completely encircled the viscus, leaving only ½ inch of the anterior wall uninvolved. It was ulcerated in the centre, while the rest of the surface presented a honeycombed necrotic appearance, save at the extreme margin. The bile papilla and opening of the common duct were situated about an inch below the tumour, and appeared normal. Between the papilla and the lower margin of the growth, and immediately abutting on the latter, there was a diverticulum about ¾ inch in depth, and just wide enough to admit the tip of the little finger. The common duct, where it lay in relation to the duodenal tumour—that is, about an inch below the junction of the cystic and hepatic ducts—was itself the seat of an annular new growth completely encircling the lumen, and apparently directly continuous on its deep aspect with the duodenal growth. Above the tumour there was marked dilatation of all the bile passages, gall bladder, common duct, cystic and hepatic ducts, but that the obstruction was anatomically incomplete was shown by the ease with which a probe could be passed through the stenosed portion of the tube, and so through the remaining portion of the common duct to the intestine. The dilated bile passages, both intra- and extra-hepatic, were filled with a thin slightly bile stained, mucoid fluid, while their walls presented a curiously pitted appearance.

The liver on section was soft and fatty looking, and showed a considerable degree of bile staining, especially around the dilated hepatic ducts. There were several secondary deposits of new growth, of which the largest, about the size of a hazel nut, was necrotic and bile stained in the centre. The pancreas presented no evidence of new growth, but several of the lymph glands in relation to it were the seat of secondary deposits. The spleen was fibrous but of normal size. There was an accessory spleen the size of a hazel nut immediately above and in front of the left adrenal. The latter *glands were of very large size, and the brown zona* reticularis was unusually prominent. The kidneys, which were markedly bile stained, were of small size, and were embedded in a very large amount of fat. On section, cortex and medulla were badly differentiated, although the former was not unduly narrow. There were several small puckered depressions on the surface of both organs, clearly the result of a starvation fibrosis.

---

[1] American Journal of the Medical Sciences, 1904, vol. cxxviii., p. 824 (Bibliography).

The lungs were emphysematous, congested, and somewhat œdematous, and there were old pleural adhesions on the left side. The aorta was bile stained and contained several atheromatous patches. The heart contained large agonal thrombi extending into the aorta and pulmonary artery on each side. The mitral valve showed marked thickening of the cusps and of the chordæ tendineæ, but there was no stenosis. The other viscera, including the stomach, presented no features worthy of note.

Microscopic examination.—Various portions of tissue were taken for histological investigation as follows: (1) Duodenal growth, (2) growth in common duct, (3) nodule in liver, (4) lymph gland deposits, and (5) pancreas. The general structure of the tumour is definitely cancerous, and for the most part the type is that of an adeno-carcinoma. This is best seen in the case of the lymph gland deposits and in the liver nodules, where the acini are large and well developed, being separated in the more central parts by a considerable amount of fibrous stroma. In the duodenal and common duct tumours, however, there is well-marked evidence of anaplasia, a reversion to a spheroidal cell and mixed cell type of growth without acinar formation. In these situations the cells show great variation in size and shape, and not a few are possessed of multiple nuclei, but mitotic figures are comparatively few in number. Many of the cancer cells, especially in the larger alveoli, show degenerative changes, both mucoid degeneration and varying degrees of necrosis. There are areas of massive necrosis in the centre of the duodenal tumour, in the larger liver nodules, and in the glands related to the pancreas. The duodenal tumour is fairly well defined at the margin, but it has extended through the whole thickness of the bowel wall, and is in direct continuity with the deep aspect of the common duct growth. The histological appearance of these two tumours is precisely similar, in our opinion strongly indicating that one is secondary to the other. The pancreatic tissue, while not actually invaded, is in direct contact with the lymph gland deposits. It presents a normal appearance, with large and prominent islets of Langerhans. The liver is the seat of advanced cloudy swelling, proceeding in parts to actual necrosis of the hepatic cells. Where it surrounds the carcinomatous nodules the liver tissue is compressed and infiltrated by the new growth.

Comment on the clinical diagnosis of this case need not be laboured by conjuring up fanciful possibilities, for the problem unravels itself up to a point, beyond which we enter upon the domain of pure speculation. That the trouble did not lie in the head of the pancreas was fairly obvious, for the gall-bladder was not distended, and signs of pancreatic insufficiency were wanting. A diagnosis of enlarged glands in the portal fissure secondary to disease in the stomach did not meet the facts of the case, owing to the absence of physical signs in that organ and absence of ascites. Primary malignant disease in the first part of the duodenum, a diagnosis of which is dependent upon the signs of pyloric obstruction, was equally unsatisfactory as a solution of the problem. Lastly, primary malignant disease of the common bile-duct as the only cause revealed obvious shortcomings, and however impatient one might be of ignorance, the only logical outlet from the *impasse* was, as Dr. Barrs pointed out, to wait and see which of the two latter conditions post-mortem examination would show to be the cause of the man's death.

From the pathological standpoint the chief problem for solution was, Which was the primary growth—that in the duodenum or that in the common duct? The possibility that we had to deal with two separate tumours of independent origin was almost too remote to be worthy of consideration, but it may be pointed out here that not only were the tumours in this case precisely similar in histological structure, but they were directly continuous with one another. After careful consideration we have come to the conclusion that the duodenal tumour was the primary, and for the following reasons: 1. The gastric symptoms were of three months' standing, whereas the jaundice had only been in existence one month. 2. The type of tumour was very suggestive of a carcinoma of bowel origin. 3. There were secondary deposits in the liver and lymph glands, an event which occurs more frequently and earlier in duodenal cancers than in those of common duct origin. 4. The duodenal tumour was more extensive and the seat of more advanced degenerative changes than the common duct growth.

That the tumour was of a highly malignant character was shown both by the rapidity with which it killed the patient and by the presence of hepatic and glandular dissemination. The histological characters, showing reversion to a spheroidal cell and mixed cell type of growth, also bore this out.

We are indebted to Dr. Barrs for permission to publish the above notes.

METHODS OF INCREASING THE ACCURACY AND DELICACY OF THE WASSERMANN REACTION.[1]

BY FRANCIS H. THIELE, M.D., B.SC. LOND., F.R.C.P. LOND.,
LECTURER IN BACTERIOLOGY IN UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL;
AND
DENNIS EMBLETON, M.A., M.B. CANTAB.,
ASSISTANT LECTURER IN BACTERIOLOGY IN UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THE Wassermann reaction is not a complement fixation reaction brought about by the interaction of a true specific syphilitic antibody in the patient's serum with the syphilitic spirochætes. The antigenic value of the antigen used in the original reaction has no relationship to the richness of the organ in spirochætes—in fact, an emulsion of spirochætes as antigen gives only very feeble complement fixation, if any, with a syphilitic serum. The only other possible way in which the original antigen as used by Wassermann might be superior to others derived from non-syphilitic sources might be that the organ from which the antigen is made contained products of the action of the spirochæte, which might cause complement fixation with a syphilitic serum. If this were so the antigenic value should be directly proportional to the spirochæte content, which it is not. For this reason the original Wassermann reaction has no claim for superiority over any subsequent modifications.

---

[1] A paper read before the Pathological Section of the *Royal Society* of Medicine on Feb. 3rd, 1914.

We consider that the antigenic value of an antigen depends on the degree of autolytic degradation that it has undergone before extraction. As the original Wassermann antigen was extracted from organs which frequently showed various degrees of autolysis, this antigen was more frequently antigenic than those used in later modifications. By reference to the following table (Table I.) it will be seen that a syphilitic fœtus liver rich in spirochætes only acted as a good antigen when it had undergone a certain degree of autolytic degradation. We were fortunate in being able to obtain a syphilitic fœtus which died during delivery, so that we could obtain a perfectly fresh liver for testing. The fresh organ (1) showed practically no antigen value; the same organ (2) when autolysed showed a good antigenic value. The rest of the table shows that the autolysed condition of the organ and not its spirochæte content confers the antigenic value on extracts made from it. All the modifications introduced in the Wassermann reaction show that the trouble throughout has been to obtain a powerful reliable antigen. In order to get over this trouble the latest modification, the addition of cholesterin, has been introduced. Now cholesterin cannot act as an antigen; it can only act by inhibiting the action of complement, and thus mask the complement which is left unbound by the feeble antigen.

TABLE I.—*Showing the Dependence of Antigenic Value on Autolytic Degradation and not on Spirochæte Content.*

No.	Description of antigen.	Hæmolytic titre.					Sections showed.
1	Syphilitic fœtus liver; child died during delivery. Fœtus frozen, liver extracted 12 hours later.	c.mm. 500	c.mm. 300	c.mm. Slight (300)	c.mm. ?	*Nil.*	Numerous spirochætes.
2	Same liver, autolysed three days, room temperature.	400	100	40	Slight (60)	"	"
3	Liver (congenital syphilis) fairly fresh.	500	300	100	Slight (100)	"	"
4	Liver (congenital syphilis), slightly macerated fœtus.	400	60	30	60	"	Few spirochætes
5	Liver (congenital syphilis), fairly fresh when obtained, autolysed for three days, room temperature.	400	80	80	100	"	"
6	Liver (congenital syphilis), fœtus showing maceration; liver very autolysed.	300	80	60	100	"	Numerous spirochætes.

The organs were first dried in vacuo and finely powdered. A 1 in 10 suspension was made in normal saline. This was shaken mechanically for 6 hours and centrifuged. The clear supernatant fluid was used as the antigen.

As a result of our investigations we have come to the conclusion that not only is it unnecessary but unsafe to use an anticomplementary antigen, and still more so to add further anticomplementary substances. In the first place, it is easy to obtain with absolute certainty a really powerful antigen for the reaction, free from all anticomplementary substances, so that as little as 0·000003 grm. of this antigen will, in the presence of syphilitic serum, cause complete fixation of the quantity of complement used in the Wassermann reaction. The antigen is a purified phosphatid, having the nitrogen phosphorus ratio, N_1P_1. obtained from an organ *autolysed* at room temperature for 24–36 hours.

Table II. shows that the antigenic value of a phosphatid depends upon the degree of autolysis of the organ from which it is obtained. (The smaller the quantity which contains the unit of antigen the stronger the antigen.) The organs were obtained immediately on the death of the animal, cleaned and minced while still warm, and divided into several parts. One part was dried at once in a current of warm air and desiccated *in vacuo*. The other parts were autolysed at room temperature for 18, 24, 36, 48, and 72 hours. The N_1P_1 phosphatids were obtained from each portion, were purified until they were no longer anticomplementary or hæmolytic, and were put up at 3 per cent. in absolute methyl alcohol. From the methyl alcohol solution a 10 per cent. suspension was made in normal saline.

Now, looking at Table II. we see that the fresh organ phosphatids *possess no antigenic properties*. In 18 hours these properties begin to develop, they are at their maximum from 24–36 hours and then begin to wane. All the phosphatids can act as good antigens provided they are extracted from suitably autolysed tissues. The only reason for using the N_1P_1 fraction is the ease with which it can be handled.

TABLE II.—*Showing that the Antigenic Value of a Phosphatid depends on the Degree of Autolysis.*

No.	Heart I.		No.	Kidney II.

* Antigenic in = complete fixation of 2 units of complement in the presence of *100 c.mm. of inactivated syphilitic serum with this quantity* of the phosphatid suspension.

The Fallacy of Using Anticomplementary Substances for Increasing the Delicacy of the Reaction.

We have been investigating the means of increasing the delicacy of the Wassermann reaction and have come to the conclusion that the addition of anticomplementary substances besides being unnecessary introduces a fallacy in the reaction. As we shall show next, the magnified complement inhibition which occurs when an anticomplementary substance like cholesterin is added to syphilitic serum and antigen, is not characteristic of syphilis as is stated by Browning and MacKenzie, Sachs, and others. It also always occurs when an anticomplementary substance, like cholesterin, is added to an already anticomplementary mixture. First of all, Table III. shows what we have called the "anticomplementary adjuvant phenomenon." Experimenting with the serum of a non-syphilitic corpse (1) 40 c.mm. of this is found to be anticomplementary to less than ¼ of a unit of complement. (2) Now 80 c.mm.—i.e., twice this amount—should be anticomplementary to less than ½ a unit, but when tested it is found to be anticomplementary to 1¼ units. (3) We have 200 c.mm. of a cholesterin suspension; this is anticomplementary to less than ¼ of a unit. (4) Now 400 c.mm. of the cholesterin should be, at this rate, anticomplementary to ½ a unit, but when tested it is found to be anticomplementary to more than ¾ of a unit. (5) Now if we take a mixture of 40 c.mm. of corpse serum and 200 c.mm. of cholesterin we might expect it would be anticomplementary to less than ½ a unit, but when tested we find it anticomplementary to more than 1¼ units. Thus, when dealing with a mixture of substances of very slight anticomplementary power, we get a fixation of complement considerably greater than could possibly be expected from estimating each separately, and which would in a Wassermann reaction have been regarded as indicating a slight positive reaction.

TABLE III.—*Showing the Anticomplementary Adjuvant Phenomenon.*

No.	—	Complement. Units ... ... / Quantity in c.mm. ...	1 20	1¼ 25	1½ 30	1¾ 35	2 40	2¼ 45	2½ 50	Anticomplementary power. Calculated.	Proved.
1	Serum Corpse E	40 c.mm.	VMH	C	C	C	—	—	—	—	Less than ¼ unit.
2	Serum Corpse E (as 1)...	80 c.mm.	SH	SH	SH	SH	MH	MH	C	Less than ½ unit.	More than 1¼ units.
3	Suspension of cholesterin.	200 c.mm.	VMH	C	C	C	—	—	—	—	Less than ¼ unit.
4	Suspension of cholesterin (as 3)...	400 c.mm.	SH	SH	MH	MH	C	C	C	Less than ½ unit.	More than ¾ unit.
5	Serum Corpse E (as 1) + cholesterin (as 3)... ...	40 c.mm. 200 c.mm.	SH	SH	SH	MH	MH	MH	C	Less than ½ unit.	More than 1¼ units.

The anticomplementary substances and complement were added together and the bulk brought up to 2 c.c. with normal saline. The mixture was incubated for 1 hour and then 1½ units of amboceptor and 1 unit of red cells added. C = Complete hæmolysis. VMH = Very marked hæmolysis. MH = Marked hæmolysis. SH = Slight hæmolysis.

In Table IV. we see another example of the adjuvant phenomenon, the influence of cholesterin in the Wassermann reaction: (1) shows us a phosphatid antigen which in the quantity used is not anticomplementary; (2) is a Wassermann reaction with a weak syphilitic serum; (3) is the anticomplementary power of the added cholesterin; (4) shows how enormously the addition of cholesterin apparently magnifies the Wassermann reaction (compare 2). So that at first sight it appears that cholesterin has a very remarkable influence on the Wassermann reaction, making a weak serum give a powerful result. Now turning to (5) we have here a normal serum which has been allowed to stand and has developed anticomplementary powers. In the quantity used it will be noticed that this serum inhibits as much complement as (2) (the syphilitic serum and antigen mixture). Now (6) shows that when cholesterin is added to this anticomplementary normal serum we get as much fixation as occurred in (4). (7) and (8) show that there is no increase in complement inhibition on adding the anticomplementary serum to a non-anticomplementary antigen. The serum in (5) is anticomplementary to 1½ units, the cholesterin to 1 unit. The mixture of these two would be expected to be anticomplementary to 2½ units; in reality it is to more than 5 units—that is, more than double what is expected.

TABLE IV.—*Showing the Influence of Cholesterin in the Wassermann Reaction.*

No.	Complement Units ... / Quantity ...	1 20	1½ 30	2 40	2½ 50	3 60	3½ 70	4 80	5 100	6 120	Units of complement interfered with.
1	Phosphatid antigen	C	C	C	C	C	C	C	C	C	0
2	Phosphatid antigen (as 1*) + syphilitic serum	SH	MH	VMH	C	C	C	C	C	C	1½
3	Phosphatid antigen (as 1) + cholesterin emulsion	SH	MH	C	C	C	C	C	C	C	1
4	Phosphatid (as 1) + cholesterin (as 3) + syphilitic serum (as 2)	O	O	O	O	O	O	O	SH	SH	More than 6.
5	Anticomplementary normal serum ...	SH	MH	VMH	C	C	C	C	C	C	1½
6	Anticomplementary normal serum (as 5) + phosphatid antigen (as 1) + cholesterin (as 3)	O	O	O	O	O	O	O	SH	SH	More than 6.
7	Anticomplementary normal serum (as 5) + phosphatid antigen (as 1)...	SH	MH	VMH	C	C	C	C	C	C	1½
8	Anticomplementary normal serum (as 5) + another phosphatid antigen (not anticomplementary)...	SH	MH	VMH	C	C	C	C	C	C	1½

* (as 1) = in the same quantity as in Experiment 1. C = complete hæmolysis. VMH = very marked hæmolysis. MH = marked hæmolysis. SH = slight hæmolysis. O = no hæmolysis.

Thus, we see that cholesterin merely magnifies any anticomplementary effect, whether already present or induced by the Wassermann reaction. It is owing to the failure to appreciate this "*anticomplementary adjuvant phenomenon*" that people who use anticomplementary antigens are continually reporting positive Wassermann reactions with anticomplementary sera from corpses, after anæsthetics and hypnotics, and in scarlet fever, &c.

We would not for a minute dispute the fact that cholesterin has been of undoubted value in enabling a reading to be obtained by magnifying the slight degree of complement fixation occurring when a syphilitic serum is exposed to a weak antigen, but the addition of cholesterin is the confession of a weak antigen and is absolutely unnecessary if the antigen used is sufficiently powerful. In addition it introduces sources of error, it may be only in a small percentage, which the use of a powerful non-anticomplementary antigen avoids. Some cases are apparently positive when they should be negative, the result being purely due to the summation effect of two pre-existing anticomplementary factors. On the other hand, others are missed, the failure to get a positive result being due to the feeble antigenic power of the antigen used. The complement fixation here is so small that it is not appreciably magnified by the adjuvant effect of the cholesterin.

In conclusion: 1. It is always possible to have an extremely powerful antigen which will keep its power unaltered for months. 2. It is possible to have an antigen which is not anticomplementary, so that summation and adjuvant phenomena cannot play a part in the reaction. 3. The use of cholesterin and other anticomplementary substances in antigens for the Wassermann reaction is not only unnecessary, but introduces a very serious source of error.

Our method of increasing the delicacy of the reaction is: 1. To diminish the amount of complement used to 1½ times only, that which will cause complete hæmolysis of the system adopted. 2. To [illegible] *a cubic centimetre or more,* [illegible] serum. 3. To use 50 to 100 [illegible] By this method purely anticomplementary phenomena do not play a part. Anticomplementary effects being rendered obvious in the control, true complement fixation, even when minimal, can be readily demonstrated. In this way (1) cases which would otherwise give a slight reaction, so slight as to be doubtful on the ordinary reaction, give a full fixation; (2) cases which otherwise give a negative can be made to give a full reaction, thus bringing in a large number of latent cases; and (3) no fallacious results with other diseases have been obtained.

DECOMPRESSION OF THE BRAIN IN INTRACRANIAL HÆMORRHAGE:

THE VALUE OF THE OPERATION IN CASES THE OUTCOME OF ACCIDENT OR DISEASE.[1]

BY L. BATHE RAWLING, M.B., B.C. CANTAB., F.R.C.S. ENG.,
SURGEON WITH CHARGE OF OUT-PATIENTS TO ST. BARTHOLOMEW'S HOSPITAL.

I propose dealing with the question of decompression from the point of view of injury only, and that also from a clinical aspect. The wording of the subject for discussion is sufficiently clear. We are not asked in any way to express our views with regard to the desirability of operation for such localised hæmorrhages as middle meningeal hæmorrhage, subdural hæmatoceles, &c. The subject matter is strictly confined to a discussion of the advantages that may be obtained by decompression for the *average* case of head injury, for doubtless you will agree with me when I state that the average case of head injury is lacking in the essentials of localisation, all localising symptoms being obscured or completely lost in the general clinical picture of concussion or compression.

We are asked, therefore, to discuss decompression in relation to concussion and compression, and we can at once exclude all the minor grades of concussion. They are obviously of such a type as to require no operative treatment whatsoever. We are thus left with the more serious and prolonged cases of concussion and cases of definite compression. Taking the former type first—the grave concussion cases—my experience tells me that the mortality in such cases is exceedingly high, the outlook most grave, and that the majority die within 36 to 48 hours, without evidencing the slightest attempt at reaction, with a markedly subnormal temperature, a rapid pulse-rate and a lowered blood pressure, the latter symptoms being referable to the cardio-vascular depression.

Now, insomuch as the prognosis in these cases is so grave and that of compression is relatively hopeful, I am of opinion that we ought to adopt heroic measures, utilising every means in our power to force on a stage of reaction, more especially by the adoption of rectal or intravenous infusion, even at the risk of so raising the blood pressure as to bring on fresh bleeding within the skull. If the stage of reaction *can* be induced the patient will probably pass from the stage of profound concussion into that of definite compression, a condition affording some hope of a favourable issue if decompression measures are carried out at the right time and in the right manner. I think that such cases *may be included amongst those requiring decompression.*

Still, it is those well-defined cases which are, so to speak, compressed at an early stage which so urgently require operative treatment, cases in which the patients, after passing through the initial stage of concussion, common to all cases of head injury, exemplify the more typical symptoms of compression within a few hours of the accident. There can, I think, be but little doubt that such cases urgently demand decompression. For the purpose of argument, let us take the symptom-complex of well-developed compression, the so-called "manifest" stage. Here I quote from Kocher: "There is widespread capillary anæmia. The medulla is markedly affected. The period of vaso-motor regulation has set in with its high blood pressure, and this, with its vagal quality, gives the pulse its bounding character. The rise in blood pressure shows a definite rhythm. There are also rhythmic alterations in the size of the pupils, with alternate increase and decrease in the depth of stupor, so that the up-wave causes the patient to moan, become irritable, and thrash about, whilst the down-wave sees him completely comatose. The pulse is markedly affected, the respiration becomes rhythmic and Cheyne-Stokes in character, and the discs evidence pronounced choking. All reflexes are abolished, cyanosis is extreme, and respiration snoring."

This is the picture of "manifest" compression, a graphic illustration of the fight that is being put up by the vital centres against the increased, and perhaps increasing, intracranial pressure, a struggle for existence which will almost certainly terminate against the patient unless all possible reinforcements are brought to his aid. Our general attitude towards this state of affairs is inexcusable. We stand by and do nothing, with the almost inevitable result that the patient passes into the paralytic stage, a stage characterised by increasing rapidity of the pulse-rate, a steadily falling blood pressure, increasing coma, muscular relaxation, and respiratory paralysis.

---

[1] A paper introductory to a discussion on Decompression of the Brain at the Medical Society of London on Feb. 9th, 1914.

In fatal cases definite evidence is always to be obtained as to the pathological conditions leading up to compression, hæmorrhages in relation to the membranes, laceration of the brain, and cerebral œdema, and it is clear that it is the increasing intracranial pressure which induces the compression symptoms. Now Leonard Hill's experiments showed that a very slight increase of intracranial tension, anything over 5 per cent. of the intracranial capacity, will suffice to bring about these compression symptoms. Very little will induce compression, and very little will relieve it when present. Take, for example, a case of cerebral contusion with secondary spreading œdema. The cerebro-spinal tension and intracranial venous pressure are practically equal under normal conditions, but in the case in question the venous engorgement and the consequent increased intracranial venous pressure is at once followed by a transudation of fluid from the veins into the meshwork of the pia-arachnoid, into the cerebral substance and into the subdural space. Such excess of fluid is found in all cases, whether at the operation or in such fatal cases as come to necropsy. A decompression operation, even if it fails to bring to light the existence of an extradural or subdural extravasation or area of brain laceration, will at any rate allow of the escape of some of the fluid, will diminish the degree of compression in direct proportion to the amount of fluid escaping, and will allow of time for the recovery of the medullary centres.

I think it must be accepted, both from the theoretical and clinical points of view, that decompression is urgently demanded in suitable cases, where the temperature is steadily rising, where unconsciousness is deepening, where the blood pressure is high and the pulse-rate slow. This is the critical time in the case, and this is the moment at which decompression should be carried out. To wait longer courts disaster. To decompress a patient in the later or paralytic stage of compression, when the pulse-rate is increasing, the blood pressure falling and respiration failing, is an unsatisfactory method of treatment. Still, it is quite justifiable because by the decompression operation some intracranial hæmorrhage may be discovered and the tide thus turned in favour of the patient. Such operations, however, are more exploratory than decompressive.

The value of decompression being acknowledged, I would raise the question as to the decompressive assistance which may be obtained by *lumbar puncture* and *venesection*, either by themselves or in conjuction with a decompression operation.

First, with regard to *lumbar puncture*. In my opinion it is utterly useless for the relief of compression which is dependent on intracranial injuries, though repeated time after time. In addition, there is a positive danger that the sudden escape of cerebro-spinal fluid and blood may lead to the medulla being forced down into and "corked up" in the foramen magnum, with immediate disastrous results. Such an accident not infrequently happens when lumbar puncture is carried out for neoplasms of the brain, and I have seen the same disaster occur in traumatic cases. On the other hand, I consider that considerable benefit may be derived from *venesection*, both in mild cases of compression when carried out alone, and in the more serious cases when utilised in conjunction with decompression operations. The benefits derived, unquestionable from my personal experience, are in all probability dependent on the reduction of the intracranial venous pressure and the consequent diminution of the degree of cerebral œdema.

Some decompression operation being decided on, what is the best method? There are two chief operations, *cerebellar decompression* and *subtemporal decompression*. In comparing the relative advantages and disadvantages of these two methods, it is necessary to take into consideration the critical condition of the patient, and I think that the method chosen should fall into line with the following desirable features:—

1. Insomuch as the vital centres are in a most unstable position—more especially the respiratory centre, which almost invariably gives out first—the operative position should be one in which there is as little disturbance of respiratory function as is possible. In other words, it is of importance that the patient should be on his *back*.

2. The *site* chosen for the operation should be a convenient one for the surgeon, so that the attack can be carried out deliberately.

3. *Hæmorrhage* should be capable of control during the operation. The sudden loss of any quantity of blood will imperil the action of the vagus and vaso-motor centres, both of which are in a position of considerable instability.

4. An *area* should be chosen where the skull is thin, so that the trephining and enlargement of the gap may be carried out expeditiously and with the least disturbance to the patient.

5. The area "*attacked*" should be a "*likely*" area, one where hæmorrhage in relation to the membranes or where brain laceration is likely to be found.

6. The *region* of brain exposed should be a "*silent*" area, for the sudden relief of intracranial pressure may lead to such protrusion of the brain that disastrous results will ensue in the event of the motor area or cerebellum being involved.

7. The *relief* of intracranial pressure should be *gradual* in character, not sudden and violent.

Taking these factors into consideration with respect to *cerebellar* decompression, it is clear that this particular method is lacking in many essentials. Admittedly, the operation is conducted in close relation to the medullary centres, with proportionate pressure relief, but the relief is *too drastic*. Again, the position required for the operation is bad for the patient and most inconvenient for the surgeon. Respiratory failure is always to be feared in cerebellar operations, and hæmorrhage may be profuse and difficult of control. Altogether this operation is not to be commended. In previous years I regarded it as the operation of choice and carried it out on several occasions. I doubt, however, whether I have ever saved a life by cerebellar decompression. I have abandoned this operation.

On the other hand, take *subtemporal* decompression, the intermusculo-temporal method of Harvey Cushing. This particular operation fulfils all the requirements of a satisfactory decompression. The patient is on his back, and respiration is not interfered with. The site is a convenient one for the surgeon, and hæmorrhage may be kept under control, first by pressure over the superficial temporal artery, and secondly by quiet and deliberate methods of operation. In addition, the skull is thin, readily trephined, and readily cut away according to requirements. Consider now the relation of the operation to "likely" and "silent" areas. It is conducted over the territory of the middle meningeal artery, and *injuries of this vessel are of frequent occurrence* though they may not, and usually do not, give rise to the so-called typical symptoms of a middle meningeal extravasation. Again, the region of brain exposed is the front aspect of the temporo-sphenoidal lobe, an area of brain lacerated with greater frequency than any other part of the cerebrum or cerebellum. In consequence, I regard subtemporal decompression as the method of choice.

With regard to the *side* on which the operation should be conducted, there can be no question that in all doubtful cases—that is to say, in cases devoid of all localising symptoms—the decompression should be carried out on the *right* side, thus avoiding any possibility of including in the hernial protrusion the motor speech area of Broca. I have a clear recollection of one case in which a left-sided operation was conducted rather too high, and which resulted in well-marked motor aphasia, fortunately of a temporary character only. In all cases, however, one is guided in the choice of side by the site at which the blow was applied, by an examination of the fundus, and by a critical investigation into the temperature on the two sides of the body. Thus, if the blow was received in the right occipital region it is probable that the left temporo-sphenoidal lobe is the site of the laceration—laceration by *contrecoup*—and the operation is there conducted. Again, if there is any marked congestion of the discs the operation is carried out on the side on which the change is most pronounced. Finally, in the event of any marked difference in the temperature on the two sides of the body, the decompression is made on that side which shows the greater elevation of temperature.

Blood pressure records taken during the course of the operation will enable the operator to appreciate whether a sufficient relief has been attained. If not, the same operation is carried out *on the opposite side* as well.

There may be some difference of opinion with respect to the *size of the opening* which it is necessary to make in the skull, but my experience tells me that, within certain limits, the larger the opening the greater the degree of decompression. The comparative small size of the opening obtained in a subtemporal operation has been regarded as a point against this particular operation. I feel sure, however, that, by forcible retraction of the temporal muscle, one is enabled to obtain an opening of sufficient size, it being borne in mind that the decompression should be gradual, not violent.

With regard to the desirability of *opening the dura mater*, whatever difference of opinion may be existent with respect to this course in the palliative treatment of neoplasms of the brain, there can be no question that the membrane must be opened, and that freely, in all decompressions for injury. It is only by such means that a real decompression may be brought about, blood and cerebro-spinal fluid draining away into the tissues of the temporal region, where, under favourable circumstances, they are reabsorbed.

Now, with regard to the *technique of the operation.* Shaving of the head may be confined to a limited area, ample margin, however, being allowed for the conduction of the operation. The skin is sterilised with iodine, after which the head is covered with a sheet of gauze four layers thick, space being allowed for the administration of the anæsthetic if such should be required. During the *operation blood-pressure records should be taken* every few minutes, following the various stages of the operation, the assistant reporting to the surgeon the changes that may take place.

Efficient *hæmostasis* is of great importance, for reasons previously stated. Whilst an assistant compresses the superficial temporal artery as it passes over the base of the zygoma an incision is made through gauze and skin, which commences one inch behind and above the external angular frontal process, curves along the temporal crest, is then directed downwards towards the zygoma, and terminates immediately in front of the tragus of the ear. This incision falls short, at its commencement, of the external angular frontal process with the object of avoiding that branch of the facial nerve which passes forwards to the anterior belly of the occipito-frontalis muscle. The incision, lightly made, includes the skin and subcutaneous tissues only, the various branches of the superficial temporal artery being seized by the assistant as soon as they are exposed or divided. By adopting these precautions the total amount of blood lost is quite inconsiderable.

The flap—comprising skin, subcutaneous tissues, and the superficial temporal artery—is turned down towards the zygoma. At the base of the flap care must be taken to avoid wounding the artery, this vessel being responsible for the nutrition of the flap. The temporal fascia is now exposed. It is also turned down as a flap, the line of incision falling immediately short of the skin incision. The temporal muscle, now exposed, is split in the direction of its fibres, in the centre of the field, from above downwards, and forcibly retracted on either side.

For *trephining* it is necessary to have such an instrument as will work [illegible] least possible danger of [illegible] structures. For example, [illegible] meningeal artery during the process of trephining complicates the *operation and adds needless risk* to the procedure; the patient is not in a condition to stand any serious hæmorrhage, such as may well occur before the bleeding points can be secured. The older hand-trephine, though fairly safe in experienced hands, always presented the disadvantage in that the artery and *dura mater* were liable to injury. In this modern instrument there is no such danger. It is stated, and I think truly so, that you could not injure the dura mater if you tried. The mechanism of the trephine is such that it ceases to work, or requires excessive force to make it work, so soon as the resistance is overcome—that is to say, as soon as the internal table is perforated. It presents one disadvantage only—the trephine hole is small. With suitable bone-cutting instruments, however, this is easily overcome.

The trephine is placed over the angle between the anterior and posterior branches of the middle meningeal artery. In spite of such precautions, however, it is not always possible to avoid an immediate exposure of the main trunks, a fact which appears at first sight as a disadvantage to this operation in general. As previously stated, however, there is but little chance of actually wounding the vessel under modern methods of trephining.

After perforation of the bone the dura mater is stripped away from the under surface of the bone and the gap enlarged with craniectomy forceps, of which no better type exists than Horsley's parrot-billed forceps. They are admirable instruments so long as the operator is contented with "small bites at the cherry," small fragments being removed at each time. The bone is cut freely away, downwards to the base of the skull, forwards and backwards so far as the retracted temporal muscle permits, whilst in the upward direction the process is more sparingly conducted, thus avoiding any possibility of including Broca's area and the lower motor areas in any hernial protrusion that may ensue after the opening of the dura mater. The gap in the bone should be oval in shape, about 3 by 2 inches, the long axis in the antero-posterior direction and parallel to the line of the temporo-sphenoidal lobe.

Before *opening the dura mater* it is necessary to underrun and ligature the various branches of the middle meningeal artery on either side of the lines proposed for dural section. The membrane is opened by crucial incision, all possible care being taken to avoid injury to the underlying congested cortical veins. The brain is probably at high pressure and at once bulges out when the membranous capsule is incised.

The *brain exposed*, the temporo-sphenoidal lobe, may be lacerated and obscured by blood clot, it may be œdematous or normal in appearance. In the first case, when lacerated, all blood clot is washed away by low-pressure irrigation with saline solution at a temperature between 110° and 115° F., after which a small rubber drain is inserted so that the distal end lies in relation to the opening in the skull and dura, the proximal end being brought out between the otherwise approximated temporal muscle and through a special button-hole in the skin. This drain should remain in position for 36 to 48 hours, after which it is shortened day by day.

When the brain is the seat of a spreading œdema or normal in appearance, the dural flaps remain open, the temporal muscle is brought together with a few catgut stitches, the temporal fascia replaced in the best position possible, and the skin sutured with interrupted silk or salmon-gut stitches.

With regard to after-treatment, morphia is of the greatest value and should be administered freely. It keeps the patient quiet and lessens the degree of shock.

In addition to the *advantages already claimed* for the subtemporal method of decompression there are others: the scar is inconspicuous, concealed by the hairy scalp, the protrusion of the brain is protected and restrained by the temporal muscle and fascia, receding in direct proportion to the recovery rate of the patient, and the gap in the skull is adequately protected by the overlying muscle and fascia.

So far as *results* are concerned, it must be borne in mind that we are dealing with the most severe lesion that the human body can be subjected to, and, in consequence, that a high recovery rate is not to be expected. The surgeon will meet with many disappointments, but, from my own experience, I would urge that they are more than compensated for by certain brilliant results. I shall not trouble you with statistics. Such tables are always full of fallacies, and errors are especially liable to be included in cases of this particular nature. Suffice it to say that the average mortality in head injuries, estimated at 50 per cent., may be reduced 10 or 15 per cent. by decompressions carried out at the right time and in the right manner.

Finally, there is another point to consider—the after-history of these cases of head injury. A large proportion of those that recover without operation suffer from the many distressing remote effects, such as headache, epilepsy, insanity, &c., and, in consideration of the pathological conditions regarded as responsible for such developments, I think it fair to argue that an exploratory decompression operation carried out at the right time will tend towards the reduction in number of such disastrous results.

Montagu-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ARTERIO-VENOUS ANEURYSM FOLLOWING OSTEOTOMY FOR GENU VALGUM.

BY W. MANSON FERGUSSON, M.D., CH.B. ABERD., L.M. ROT. HOSP. DUB.,
SURGEON, CHALMERS' HOSPITAL, BANFF.

Arterio-venous aneurysm or aneurysmal varix following an osteotomy of the femur for genu valgum must be comparatively rare, and that fact, along with the rather remarkable recovery which the case made after somewhat heroic treatment, has prompted me to record it.

A child, aged 2½, was admitted into Chalmers' Hospital, Banff, on Dec. 17th last with a note from her medical attendant requesting her admission "for immediate operation." I was informed also that the patient had been operated on for genu valgum some six weeks previously at a hospital attached to a medical school and had been discharged cured. For the week previous to admission she had been very fretty and running a slight temperature and complaining of pain in her knee.

On admission the temperature was normal and the pulse-rate was 136. The child looked very ill and would hardly allow the knee to be touched, so great was the pain. The left knee was twice the size of the right, the swelling being fairly uniform but rather more to the inner side of the joint. Fluctuation could be made out, but there was no pulsation felt. The superficial veins were enlarged over the inner side of the swelling, and there was a linear scar 1½ inches long right in the middle of the thigh immediately above the joint. I resolved to cut down upon the swelling, being inclined to think that the condition present was one of suppuration and that the reason the temperature was normal was that the child had got fairly well chilled during the railway journey to hospital.

Dr. J. C. Galloway administered an anæsthetic and I cut down upon the swelling midway between the old scar and the adductor tubercle. After getting through the skin and subcutaneous tissues I came upon a tense tissue, like the fascia lata of the thigh, between the sartorius and the vastus internus. I put on a tourniquet and then incised this swelling and found it to be an arterio-venous aneurysm formed by the popliteal vein and getting its arterial blood through a hole in the inner side of the popliteal artery. The sac was rather bigger than a turkey's egg and had exerted such pressure upon the femur that an area of the size of a shilling on the inner surface of the bone was quite dark in colour and devoid of periosteum. The hole in the artery was below the level of origin of the anastomotica magna artery and the superior articular arteries, so I ligatured the artery immediately above the hole and ligatured the vein at a point before it became enlarged. I then cut away the redundancy of the sac wall and left the wound open with a gauze drain down to the bare portion of the femur. The limb was bandaged to a splint and kept elevated for a few days, but at no time did the circulation of the foot show sign of failing. The child improved daily in appearance and rapidly became ready to be discharged with a perfectly sound leg.

If the child had been in more expert hands the procedure would probably have been vessel suture, but as I had never done any vessel suture and had no fine enough silk ready I had to have recourse to ligature of the vessels entering into the formation of the aneurysm, happily with good results.

Banff.

RUPTURE OF THE HEART DUE TO ANEURYSM OF THE MYOCARDIUM.

BY FRANK M. HUGHES, M.R.C.S.ENG., L.R.C.P.LOND.

THE subject of this note was a dock labourer, aged 49, who had never had any symptoms of heart trouble, and for the last 15 years had never been under medical treatment. He walked six miles to his work two days before his death, and then did hard work on an oil-tank each day until the third day, when he dropped down dead on the oil-tank.

At the post-mortem examination the pericardium was found to be full of blood clot. In the anterior wall of the left ventricle near the apex was an aneurysm of the size of a walnut, which had ruptured. The aneurysm communicated directly with the left ventricle. Fibrous degeneration of the myocardium at the site of the aneurysm was apparent. There was fatty degeneration of the whole heart muscle. There was no disease of any of the valves, no mesaortitis, and no atheroma in the aorta. The arteries were healthy. The liver, kidneys, and spleen were healthy. There was no evidence or history of syphilis.

The case is of interest in that the man had never suffered any pain or inconvenience with his heart. He had been a hard worker all his life, and had been passed several times as fit for work by a medical man. Also in the fact that there was absolutely no evidence or history of syphilis.

Gravesend.

ROYAL MEDICAL BENEVOLENT FUND.—A general meeting of this Fund will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Thursday next, Feb. 26th, at 5 o'clock. The annual report will be read and certain formal business transacted. It is hoped that as many as possible of those interested in the work of the Fund and its Guild will take the opportunity of meeting together. There will be no speeches, but tea will be provided.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

The Thyreoglossal Tract.—Drainage in Septic Peritonitis.

A MEETING of this section was held on Feb. 10th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. W. G. SPENCER read a paper on the Thyreoglossal Tract, which appears in full on p. 522.

Mr. HENRY CURTIS read a paper on the Most Efficient Method of Drainage in Septic Peritonitis, and for its prevention in immediate suture of perforated gastric and duodenal ulcers, &c. The object of the paper was to advocate the more general adoption of the methods of drainage taught, if not originated, by the late Mr. Bidwell, modifying the technique, however, according to the method of the author, who exhibited a drainage-tube introducer which obviated theoretical objections in Bidwell's scheme and greatly facilitated rapid introduction of the tube through the rectum, Douglas's pouch, or through the loins, in the case of subphrenic drainage, &c. (For a description and illustrations of this instrument the reader is referred to another page in this issue.) The two principles of efficient drainage for the prevention or treatment of septic peritonitis consisted in: (1) arranging for the escape of the irritating fluid (gastric or duodenal contents, &c., or actual pus) at the lowest point to which it tended to descend, rather than by the up-hill (hypogastric) route, above the pubes, commonly in vogue; and (2) routine subphrenic drainage, to prevent the frequent tendency to the formation of subphrenic abscesses, even when the general peritoneal cavity had been successfully drained after immediate suture of the stomach or duodenum. Such abscesses commonly resulted when extensive adhesions formed between the adjacent edges of the diaphragm and liver, or spleen, so shutting in the very irritating extravasations from stomach, duodenum, &c. Drainage obviated this danger. 1. Rectal drainage: It had long been the custom to drain [illegible] women, and a modifica[illegible] -men and for men would give better results in the majority of cases than drainage up-hill through a tube passed down to the floor of the pelvis through a suprapubic incision, even when a gauze wick was employed. Allusion was made to the difficulty of re-inserting the wick down to or beyond the inner end of such a tube stitched into the wound during the first few days, and a probe with two shor[illegible] usual bulbous point was [illegible] the anterior wall of t[illegible] of the prostate in men, was pierced from within out by the closed points of a large Wells's forceps. The points were made to appear per anum, where they grasped a wide drainage-tube, which was then dragged into the pelvis, so that its inner end, supplied with lateral holes, lay about one inch below the sacral promontory. The outer end was stitched to the perineum and drained into a bottle. 2 Routine subphrenic drainage. Bidwell made a vertical skin incision in both loins one inch behind and above the anterior iliac spine, and, protecting the bowel by a hand passed through the laparotomy wound, the closed points of a large Wells's forceps were thrust between the muscle fibres and so into the peritoneal cavity and out through the front wound. A tube fed into the opened blades of the forceps was dragged through the front wound and out through the loin, and its inner end was then put into the interval between the diaphragm and liver on the right side, and between the spleen and diaphragm on the left side. The tubes were sutured at their exit through the skin. Once these subphrenic and rectal drains had been inserted, the peritoneal cavity was freely flushed with several quarts of hot saline solution at 112° to 115° F., any adhesions found being gently but thoroughly separated. Objections to Bidwell's technique: 1. As to the rectal or vaginal route, the risks of drawing up a drainage-tube from without in were discussed but dismissed by Mr. Curtis as being, in his considerable experience, more theoretical than practical, provided free flushing was employed, which had the additional advantage of greatly reducing shock and immediately improving the patient's condition. To obviate the theoretical objection that Bidwell's method was "unsurgical," Mr. Curtis modified the technique and devised a cylindrical drainage-tube introducer, having one end slightly curved and blunt-pointed, to puncture with; the other end bulbous, for attachment of the drainage tube. In all cases, rectal, vaginal, or subphrenic, the tube was inserted from within out, and the inner end of the tube was then pushed into the appropriate region. Introduction could be more rapidly and safely performed by this instrument than by means of Wells's forceps. 2. As a drainage through the loins, whether of the subphrenic regions, or in cases of appendicitis abscess, which Bidwell recommended to be drained through a loin puncture, closing the front wound (except for a gauze-wick passed down to the extraperitoneal tissue, in view of infection of the abdominal wall), the objections in practice were: (*a*) that such loin-drains tended to kink sharply where passing through the abdominal wall obstructing the drainage; (*b*) the inner ends of the subphrenic drains tended to slip out of position and to protrude towards the mesial line. The same objections held for drains passed through the loin to drain an appendix abscess cavity. To obviate this difficulty Mr. Curtis inserted into all loin drainage tubes thin pewter rods, which allowed the tube to be moulded according to need and to lie snugly in the desired position, while permitting the freest drainage. A gauze wick might also be used if desired. Rectal drainage rapidly ceased, usually in from three or four days, and the tube was withdrawn accordingly. This applied also to the loin tubes. In conclusion, Mr. Curtis reported a case of overlooked appendicitis abscess in a young man who walked up to the hospital from his work on the fifth day of illness. He was found to be in a condition of most severe septic peritonitis, the distal half of the appendix being detached and discovered adherent to the anterior abdominal wall. The abdomen was full of the most offensive pus, containing streptococci and B. coli. Remarkable improvement at once followed, but after 48 hours vomiting set in and became fæcal. Paralysis of the bowel from adhesions was diagnosed on the third day, when the abdomen was therefore again opened. A distended coil of small intestine lying horizontally across the epigastric region was found and traced to a firm band attached to the great omentum in the right hypochondrium. This was divided, and recovery followed. In spite of the many triumphs already achieved, with greater vigilance, promptness, and boldness Mr. Curtis considered that the mortality from septic peritonitis was capable of being still greatly reduced, ignorance in the early stage and timidity subsequently being the two chief factors responsible for the present too high rate.

CLINICAL SECTION.

Cases in which Splenectomy has been Performed or is Contemplated for Disease.

A MEETING of this section was held on Feb. 13th, Dr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. T. R. WHIPHAM described four cases of Splenic Anæmia occurring in the father and three children of one family. He said that the incidence of this disease in two successive generations was very rare. The blood counts in them all were very similar and the differential counts were practically identical. The lymphocytes and polymorphonuclears were correspondingly increased. The red cells were diminished and showed alteration in size, shape, and nucleation. Another feature was eosinophilia, which could possibly be explained by the presence of a tapeworm in the father; but this was not so in the case of the children. He did not think that splenectomy was indicated for the father and a boy who were in a fairly good state of health, but it had to be considered in the cases of the two other children (girls), who had marked anæmia and whose blood had deteriorated lately.

Mr. PERCY SARGENT showed a case of this disease after splenectomy. The patient, a girl aged 10, recovered from the operation, but six weeks later severe hæmatemesis occurred, and was followed by pyrexia and a varying amount of diarrhœa. The leucopenia was replaced by a considerable leucocytosis, but now, 13 months later, the blood had become normal except for a slight increase of lymphocytes.

Dr. GEOFFREY HOFFMANN showed a case in a girl, aged 12, from whom the spleen had also been removed. She had had hæmatemesis, epistaxis, purpura, and melæna. The blood condition rapidly improved after the operation, and was still normal more than two years later.

Dr. HERBERT FRENCH and Mr. PHILIP TURNER showed a patient, aged 5, whose case had been diagnosed as one of splenic anæmia of the infantile form, and who had rapidly recovered after splenectomy. A younger sister had a similar condition. He thought that the cause was probably syphilis, although antisyphilitic treatment had been unsuccessful.

Sir J. BLAND-SUTTON advised splenectomy for the boy shown by Dr. Whipham. He thought that the result would be so good that it would afterwards be performed for the other cases of the family, the father excepted.

Dr. G. R. WARD disagreed with the diagnosis in the family group of cases. There was slight yellowness present due to blood destruction. The blood counts were typical of acholuric jaundice.

Dr. F. PARKES WEBER agreed with Dr. Ward. If enlargement of the spleen occurred in a family in which adults as well as children were affected and was associated with anæmia, the condition was the same as that of hæmolytic jaundice, although jaundice might not be present. No member of the family had leucopenia, which was strong evidence against splenic anæmia. Dr. French's cases belonged to a class which formed a group in themselves, in which cachexia, anæmia, and splenic enlargement were associated with congenital syphilis, but antisyphilitic treatment did no good. They were not syphilitic, but were engrafted on a syphilitic base.

Sir WILLIAM OSLER said that the remittent fever accompanied by eosinophilia in Dr. Whipham's cases indicated trichinosis, in which the eosinophilia often persisted. He also considered them examples of a form of hæmolytic jaundice. He referred to the importance of distinguishing cases of congenital syphilitic cirrhosis of the liver accompanied by enlargement of the spleen and hæmatemesis from splenic anæmia. He had long urged the value of excision of the spleen in the latter, and it had been shown emphatically that this procedure produced a cure.

Dr. C. R. BOX said that the case shown by Dr. French had formerly been under his care, and he regarded the patient as an example of von Jaksch's anæmia. The case showed that splenectomy did good in that condition. He had treated a similar case in which there was slight increase of fragility of the red cells. The spleen was removed, and though the patient died from an abscess in the stump, the blood condition improved greatly. There was a connecting link between cases of von Jaksch's anæmia, of acholuric jaundice, and of the splenic anæmia of adults.

Cases of Acholuric and Hæmolytic Jaundice were shown by Dr. W. ESSEX WYNTER and Sir J. BLAND-SUTTON, Dr. J. HUGH THURSFIELD, and Sir BERTRAND DAWSON. Dr. WYNTER and Sir J. BLAND-SUTTON'S case was one of congenital acholuric jaundice which had recovered completely and rapidly after splenectomy. Dr. WYNTER said that he had found that in such cases it was usual for an excess of cells to be present after removal of the spleen, but this afterwards subsided. It looked as though there was a compensatory overproduction which persisted for a time. In considering the advantages of splenectomy one ought to regard, not only the possibility of a fatal issue, but also the chances of enjoying the full functions of life.

Dr. THURSFIELD'S case was also one of congenital acholuric jaundice which had recovered after splenectomy. He insisted on the importance of separating out such cases from those of splenic anæmia. He thought that the fragility of the red corpuscles was a definite means of distinguishing acholuric jaundice. In true splenic anæmia this was either normal or less than normal.

Sir BERTRAND DAWSON thought that they would have to recast their present classification of such cases and had had to modify his views as to the value of fragility. He recounted cases of hæmolytic jaundice without increased fragility. The jaundice was due to over-production of bile pigments, and it was possible that the spleen might be so destructive that it broke up corpuscles of normal fragility. He regarded the manufacture of the precursors of bile pigment as a function of the spleen. Fragility persisted in spite of removal of spleen, and this was so in the case on which Sir Spencer Wells had operated and which was now under his care In hæmolytic jaundice there were phases of so called bilious attacks and bile in the urine, he was in the habit of exploring the gall bladder in such cases and commonly found either gall stones or bile mud present, a condition which should be dealt with first In cases in young people a large spleen was found, but this was not necessarily so, and in older patients hæmolysis probably occurred without splenic enlargement

Dr PARKES WEBER said that the association with gall stones had been described by Gilbert, but the proportion of cases was not a large one The speaker had suggested the name "splenomegalic anæmia" for those cases where there were anæmia and hæmolysis but no jaundice He suspected that the presence of bile pigment in the blood without bile salts might be the cause of the increase of the fragility In obstructive jaundice, where both were present, there was an increased resistance

Dr JAMES GALLOWAY showed a case which he regarded as a case of *Splenic Anæmia of the Banti type* There had been very severe gastro intestinal hæmorrhages and the spleen was considerably enlarged There was no evidence of syphilis An ascites had appeared rapidly, which he suggested might be due to portal thrombosis He invited opinions as to the advisability of removal of the spleen

Mr W D SPANTON said that with the progress of surgery excision of the spleen had become justifiable In 1863-1875 the mortality was 75 per cent, in 1876–1885, 59 per cent, and in 1885–1895 16 per cent

Other speakers favoured removal of the spleen in Dr Galloway s case

Fleet Surgeon P W BASSETT SMITH showed a case of Kala azar in an adult from Malta Every fourth day the man was being treated by intramuscular injections of atoxyl and of a vaccine prepared from his own cultivated bodies obtained by puncture of the liver Constant counter irritation had been applied to the splenic area and yeast had been given to increase if possible the white cells During the 10 months he had been under treatment he had not lost ground No question of splenectomy arose in this case

SECTION OF LARYNGOLOGY

Exhibition of Cases and Specimens

A MEETING of this section was held on Feb 6th, Dr D R PATERSON, the President, being in the chair

The following showed cases and specimens —

The PRESIDENT (1) A case of Double Intranasal Dacryocystotomy for Lacrymal Obstruction, and (2) epidiascopic exhibition of diagrams and skiagrams illustrating the Intranasal Operation on the Lacrymal Sac

Dr DAN MCKENZIE (1) A case of operation on the Tear duct, and (2) a case of Thyroglossal Cyst

Mr E B WAGGETT (1) Resection of Pharynx for Carcinoma, and (2) Resection of Larynx and Pharynx

Mr CECIL GRAHAM (1) A case of Pharyngectomy for Recurrence of Carcinoma after laryngectomy three and a half years previously, and (2) ? New Growth of Ventricle of Larynx

Mr G H L WHALE (1) Advanced Gummatous Laryngitis in a patient giving an obvious luetic history and showing gummatous scars on arms, (2) Lupus of Nose, and (3) a case of Sphenoidal Sinusitis after operation showing good drainage

Mr G WILKINSON (1) Inflammatory Fixation of the Left Arytenoid following alleged impaction of a foreign body in the larynx, and (2) *Foreign Body* (a piece of book binding wire) removed under direct laryngoscopy, after having been impacted in the larynx four months

Mr H A KISCH A case of Orbital Cellulitis due to ethmoidal and frontal sinus disease

Mr J F O MALLEY Extensive Cicatricial Pharyngeal Diaphragm following Scarlet Fever

Dr P WATSON WILLIAMS Specimen to show the exhibitor s Method of Opening the Antrum Intranasally for Chronic Suppuration

Mr W STUART LOW A man upon whom a double Ogston's Operation had been performed for Chronic Frontal Sinus Disease

Dr JAMES DONELAN Case of Double Paralysis of the Superior Laryngeal Nerves in a man aged 26, in the course of disseminated sclerosis from lead poisoning

Mr O W M HOPE (1) Double Abductor Paralysis in a child aged 8, and (2) a case of a man with "Habit Grunting" with no obvious cause

Mr E D DAVIS Note of the result of treatment of the case of Unusual Adductor Paresis

Mr HUNTER TOD A case of Syphilitic Laryngitis

Dr W H KELSON A case of Fixation of Right Vocal Cord for diagnosis

Mr W DOUGLAS HARMER A case of Pharyngeal Cyst

MEDICAL SOCIETY OF LONDON.

Decompression of the Brain.

A MEETING of this society was held on Feb 9th, Sir DAVID FERRIER F R S, the President being in the chair

Mr L BATHE RAWLING opened a discussion on the Value of the Operation of Decompression in cases of Intracranial Hæmorrhage the outcome either of accident or disease His paper will be found in full on p 529 of this issue of THE LANCET

Dr P HAMILL spoke from his experience gained by experimental investigation in cats carried out by Mr J E H Roberts and himself He said that decompression was indicated in certain cases of cerebral hæmorrhage especially in those fulminant cases in which coma rapidly set in with great respiratory embarrassment In such cases death usually occurred within 24 hours It was not advocated for all cases The clinical syndrome was essentially similar in hæmorrhage, embolism and thrombosis the difference was chiefly one of degree The amount of blood effused was probably not sufficient to produce the symptoms in all cases There was no effusion in embolism and thrombosis Effusion of blood, thrombosis, or infarction of any organ or tissue was rapidly followed by the development of œdema In the brain this soon produced increased pressure The results of increased intracranial pressure were (1) Embarrassment of the respiratory centre, stertor and cyanosis, (2) rise of blood pressure, (3) slowing of the pulse (vagal inhibition), and (4) prolonged cardiac failure due to (*a*) excessive strain, or (*b*) inefficient oxygen supply to the heart, the result of the respiratory failure Three questions arose Was the rise of blood pressure intrinsically bad? Should we bleed to reduce it? Did the hæmorrhage tend to continue? Some physicians advised bleeding in cases seen early in order to produce a temporary lowering of blood pressure and thus to give an opportunity for clotting to occur There was much to be said for this practice Probably the hæmorrhage was all over in a few minutes in most cases unless rupture into the ventricle or under the arachnoid occurred In many cases the clinical history tended to support this view In animal experiments the brain herniated immediately after decompression, but did not continue to do so Rise of blood pressure was a compensatory mechanism and to lower it to any extent carried with it grave risks of respiratory failure Animals bled rapidly died Bleeding appeared to benefit some grave cases probably because the heart, weakened and dilated from lack of oxygen (the result of dyspnœa) dilated and therefore worked less efficiently, bleeding relieved the distension and allowed the heart to contract down and to resume work The intracranial pressure could be relieved by lumbar puncture or by operation Lumbar puncture was at best only a temporary measure and was not devoid of grave risk of sudden death from the formation of a pressure cone The decompression operation was an efficient method of lowering the pressure, in some cases it was not necessary to turn down a large dural flap provided that on puncturing the dura cerebro-spinal fluid flowed freely and the patient was relieved Animal experiments illustrated this point. It was a matter for the skill and experience of the operator Blood might burst through the cortex and produce rapid relief, drainage would then be necessary In most cases a general anæsthetic was not necessary, and was better avoided owing to its tendency to cause a fall of blood pressure Probably a local anæsthetic should be administered as Crile's work indicated provided there was sufficient time available to allow it to be used The chief points which might be urged in favour of operation were the following The danger was not great and was small compared with the condition of the patient The results on recovery would probably be better since there would probably be less scarring: (*a*) less destruction of brain round the clot owing to there being a smaller amount of compressed œdematous tissue; and (*b*) if the clot was turned out there was less to absorb and so a shorter convalescence. The risks of pneumonia were less if there was restoration of normal breathing. Subtentorial hæmorrhage had a very high mortality; probably many cases could be saved. Numerous successes had been recorded by various authors. It might be urged that there was risk of recurrent hæmorrhage. The size of the risk was at present unknown. It was present in all cases of cerebral hæmorrhage, and hæmorrhage might also follow thrombosis. In many case of hæmorrhage localisation of the lesion was difficult; it was probable that the site of the decompression was not of much importance. The point was under investigation.

Mr. **ROBERTS** said that there were a few points which had not been brought out by Dr. Hamill, but which appeared from their investigations: (1) That the effects of hæmorrhage were due to compression and not to the injury itself; (2) that artificial respiration should be readily obtainable; and (3) that the application of decompression to the meningeal hæmorrhages of the newly born was advisable and had been successfully performed.

Mr. C. A. **BALLANCE** said that he thought the time was not far off when all varieties of intracranial hæmorrhage would be considered as clearly surgical as were other forms of hæmorrhage. It had long been recognised that fracture of the cranial vault, when accompanied by cerebral symptoms, should be treated by operation whether there was or was not any obvious depression of bone, but the same practice was by no means so generally followed in the treatment of fractures of the base of the skull, notwithstanding that these fractures were liable to be infected by the openings of the nose, the ear, and the pharynx. The effused blood, which induced an increased secretion of the cerebro-spinal fluid and œdema of the brain, must be evacuated whether it was within or without the dura or intracerebral in location. Effusion of blood within the cranial cavity might occur from injury in such amount that life was immediately threatened, and would be destroyed if the pressure was not promptly relieved. Intradural hæmorrhage might be complicated by injury to a sinus. Such cases demanded immediate operation. Intradural hæmorrhage did not always call for immediate operation, and it was only in the later stages that such cases came into the surgeon's hands. Hæmorrhage also occurred into the subarachnoid space and into the brain itself in injuries which lacerated the brain, even when no fracture of the skull had occurred. Referring to apoplexy, he said that the chief difficulty in the study by operation of these cases was that acute apoplexy was seldom seen in hospital practice, and in operation for chronic apoplexy the best results could not be obtained. In conclusion, he would urge that operation was the rational treatment in all the types of cases mentioned, especially in fracture of the base and in acute apoplexy, which had, until now, seldom been considered as urgently demanding surgical intervention.

Mr. W. G. **SPENCER** said that he preferred the suboccipital site for decompression when the site of the lesion was unknown, and by that means often came down upon the hæmorrhage. There were certain difficulties in the way of subtemporal decompression. He always trephined cases of compression as far as he was able if the patients were going downhill. He narrated certain cases in which decompression had been performed with advantage, and one of apoplexy in which the heart improved promptly after the operation. Referring to the experimental evidence, he did not think that the results could be transferred from the cat to the human being. There were difficulties in connexion with the stimulation of the dura and cortex, which might follow the procedure employed by Dr. Hamill and Mr. Roberts, and he suggested that the dog and monkey would be the better animals for the purpose.

The **PRESIDENT** spoke with regard to the advisability of operation in cases of apoplexy. There were many questions to be answered. Which were the suitable cases? How long should one wait? Was there any great risk from damage to the brain? There were many things other than pressure to be considered in such cases. Might not another burst of hæmorrhage be produced by the operation? He said he would be very guarded in recommending the operation for spontaneous apoplexy.

HARVEIAN SOCIETY OF LONDON.

Discussion on Oral Sepsis in its Medical and Surgical Aspects.

A MEETING of this society was held on Feb. 12th, Mr. J. **JACKSON CLARKE**, the President, being in the chair.

Dr. **WILLIAM HUNTER** opened a discussion on Oral Sepsis in its Medical and Surgical Aspects. He referred to the frequency with which oral sepsis was met and the far-reaching character of its effects. Its seriousness lay not so much in its mere presence as in its association with open wounds in the mouth. The peculiar anatomical disposition of the teeth made the proximity of sepsis a particularly dangerous one. He spoke of the frequency of tonsillitis and chronic inflammatory conditions of the naso-pharynx when oral sepsis was present. Septic gastritis was a common complication. Septic anæmia arising from this source was frequently superadded to other diseases such as phthisis, nephritis, and specific fevers, and might constitute a serious disease in itself. He regarded pernicious anæmia as a disease *sui generis* but intensified by anæmia of septic origin, and treatment devoted to this factor had greatly improved the prognosis. He did not advocate such wholesale extraction of the teeth as was sometimes performed. What was needed was the advent of an era of antiseptic medicine comparable to that of antiseptic surgery.

Mr. W. H. **DOLAMORE** spoke from the point of view of the dental surgeon. He did not think that wholesale removal of the teeth was justifiable except in comparatively rare cases where severe systemic disorders followed.

Dr. C. **BUTTAR** said that he would like to ask the wholesale extractors and the vaccinists what proportion of their cases could be described as cures? and did the percentage justify the pain, the disappointment, and the distress of an edentulous lower jaw caused in those who were not benefited by the treatment? In his own practice, amongst ten patients treated by different specialists, only one professed to be relieved of his symptoms. He narrated several cases in which extreme measures had been far from satisfactory, and urged enthusiasts to consider carefully whether they were not doing rather more harm than good by this form of treatment.

Mr. G. **COATS** thought it was very questionable whether chronic irido-cyclitis was connected with oral sepsis. Post-operative inflammation might be due to it and therefore septic teeth should be removed before intra-orbital operations.

Mr. D. C. L. **FITZWILLIAMS** corroborated Dr. Hunter's view that tuberculosis of glands was engrafted on adenitis arising from oral sepsis, and agreed with him as to the importance of septic teeth in causing tonsillitis.

MANCHESTER PATHOLOGICAL SOCIETY.

Leucocytic Reaction after Repeated Serum Injections.—Perforating Ulcer of the Aorta.—Acute Perforating Diverticulitis of the Pelvic Colon.—Congenital Heart Disease.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 11th, Dr. A. **BROWN** being in the chair.

Dr. J. S. C. **DOUGLAS** read a paper on the Leucocytic Reaction after Repeated Serum Injections. In an experiment on man a leucocytosis followed the subcutaneous injection of normal horse serum and also of diphtheria antitoxin given a few days later, but when antistreptococcic serum was subsequently introduced none was observed. This failure of leucocytosis in the third experimental period was discussed, and with the aid of experiments on rabbits it was shown that neither the presence of antibody in the serum nor the induction of the anaphylactic disease would serve as an explanation, but that it was possibly due to some failure of the leucocytic system to respond to the repeated serum injections similar to that found by Jörgensen in the formation of agglutinin after repeated doses of antigen. The possible bearing of this observation on the treatment of patients with repeated injections of serums was pointed out.

Dr. P. R. **COOPER** described a case of Perforating Ulcer of the Aorta which had caused fatal hæmothorax. The patient, a man, aged 45, had complained of pain in the left side and upper dorsal region for two or three months. He was distinctly anæmic. There was no evidence of syphilis or injury, but there was a probable history of influenza shortly before the commencement of symptoms. There was absence of any confirmatory signs or symptoms pointing to spinal disease, aneurysm and gastric or duodenal ulcer or cancer. At the necropsy the left pleural cavity was filled with blood clot, and the lung and pleura were adherent to [illegible]

hole with well-defined margin about 1 inch in diameter, perforating all the coats; the rest of the aorta was normal except for some small patches of atheroma. The adjacent bodies of the fifth and sixth dorsal vertebræ were partially eroded. It was suggested that the condition might have been due to a circumscribed aortitis, probably influenzal in origin.

Mr. **JOHN MORLEY** described a case of Acute Perforating Diverticulitis of the Pelvic Colon. The patient was a man, aged 50, who was sent into Ancoats Hospital as a case of retention of urine. There was a history of pain in the left lower abdomen for a week, much worse the last two days before admission, attended with constant painful desire to micturate and great difficulty in the act. A silver catheter was passed without difficulty, and the urine, beyond containing some albumin, was not abnormal. There was frequent vomiting and absolute constipation in spite of enemata. The abdomen was generally distended and tender and somewhat rigid, but chiefly so in the left iliac fossa. There was shifting dulness in the left flank. Diagnosis lay between peritonitis due to a misplaced appendix, acute perforating diverticulitis, or thrombosis of the inferior mesenteric vessels. Operation under spinal anæsthesia revealed general peritonitis. The appendix was normal, but the pelvic colon was thickened and adherent to the bladder. In spite of peritoneal toilet and drainage the patient died five hours later. Post mortem, a necrotic perforation was found in the pelvic colon of the size of a threepenny piece. Round this, projecting into the bases of the appendices epiploicæ, were several small diverticula or herniæ mucosæ. It seemed plain that fæcal impaction in one of these pouches had led to gangrene *of the pouch and perforation. Diverticula of the pelvic* colon were found in elderly subjects with chronic constipation. The complications which might give rise to symptoms were as follows: (1) chronic thickening of the pelvic colon and plastic adhesions (peridiverticulitis), producing a mass that simulated cancer; (2) cancer might supervene on chronic diverticulitis; and (3) acute inflammation due to fæcal impaction might give rise to (*a*) general peritonitis or (*b*) a localised abscess. Such an abscess might rupture into the bladder, producing (*c*) a vesico-intestinal fistula. The adhesion to the bladder and intense pain on micturition showed that in the case under discussion such a fistula was within a little of being produced.

Dr. **CHARLES H. MELLAND** gave an account of a case of Congenital Heart Disease in which it was recognised that the heart's apex beat was to the right and the liver dulness on the left. At the post-mortem examination (the child was 1 year and 3 months old and a patient at the Northern Children's Hospital) complete transposition of all the viscera was found. The heart showed [illegible] of the pulmonary orifice, with [illegible] and patent ductus arteriosus. [illegible] that have been made that cong [illegible] result of fœtal rheumatism, or, more recently, is the result of congenital syphilis, the occurrence of the widespread developmental defect with the cardiac lesion strongly suggested that the congenital heart disease in this case, as he believed in all others, was purely a developmental defect and not in any way due to either of the two other suggested causes.

Dr. **MELLAND** also showed macroscopic and microscopic specimens from a case of Melanotic Sarcoma. The patient was admitted into Ancoats Hospital with enormous enlargement of the liver and ascites. There was a history that he had had one of his eyes removed for melanotic sarcoma some 12 or 13 years before, and at the post-mortem examination melanotic sarcomata were found widely disseminated throughout the various organs and tissues of the body. No other possible primary source was to be detected, and it was of much interest to speculate on what was happening in the long period between the removal of the primary growth and the general dissemination of secondary tumours.

Dr. **MELLAND** also showed specimens from a case of [illegible] The boy, aged 12, had had [illegible] one axilla for six years. [illegible] that period, occasionally almost disappearing under arsenic, in the way so typical of Hodgkin's disease. In the end, however, treatment had failed, and at the necropsy it was found that extensive dissemination, particularly in the abdominal organs, had occurred. The liver, pancreas, abdominal lymph glands, and kidneys were invaded and in some cases almost replaced by lympho-sarcomatous masses. Whether these were true secondary growths or were evidence of general sarcomatous transformation of pre-existing lymphoid tissue was difficult to be certain about, but the fact that the Peyer's patches were extensively involved seemed to point to the latter explanation as the most likely.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

The Presence of Complement in Infectious Diseases.—Anomalous Forms of Enteric Bacillus.—Excretion of Salt and Nitrogen in Nephritis of Scarlet Fever and Diphtheria.—Wassermann Reaction in Children from Poorer Classes.

A MEETING of this society was held in Ruchill fever hospital on Jan. 30th, Mr. **A. ERNEST MAYLARD**, the President, being in the chair.

Dr. **W. C. GUNN** discussed the Presence of Complement in Infectious Diseases. He said that in enteric fever he had found complement always present, and as a rule more abundant throughout the period of pyrexia than during convalescence. Diminution in its amount in favourable cases seemed to coincide with the production of immune body. Severity of the attack bore some relation to the amount of complement present. In patients who were very ill complement as well as immune body might be produced slowly, or only a weak type of complement might be present. *In patients moderately ill a relatively small amount of* complement seemed to indicate the presence of a considerable amount of immune body, but not sufficient to terminate the attack. In the intermediate type of illness, the most common, a large amount of complement was usually found. During relapses complement was increased, and diminished when recovery was taking place. Death from enteric fever appeared to be due chiefly to absence of immune body. Complement was sometimes very abundant in fatal cases, but at other times only a weak type might be present. Complement and immune body were not produced in any fixed ratio to one another. In the majority of cases of erysipelas examined complement was present in greater amount during the acute stage than during convalescence, the diminution apparently coinciding with the production of immune body. In diphtheria varying results were obtained. In 10 severe cases complement was greater in amount during the acute stage than during convalescence. In 5 moderately severe cases the amount was greater during convalescence. In 4 cases little or no complement was present during the whole illness, while in 2 cases of fatal diphtheria of the hæmorrhagic type complement was relatively abundant shortly before death. In 6 mild cases of scarlet fever no definite type of variation in the amount of complement occurred. In 10 more severe cases a diminution was observed during the pyretic period, with, in 6 of these, an increase during convalescence. In 4 cases of scarlatinal nephritis little or no complement was found. In 2 fatal [illegible] of complement was present [illegible] es the variations of comple- [illegible] o follow no definite rule. In [illegible]

Dr. **ADAM PATRICK** described some Anomalous Forms of the Enteric Bacillus. It was found during the investigation of bacilluria in men suffering from enteric fever that in 6 cases out of 17 the bacilli were not typhoid bacilli, but members of the typhoid-coli group, not previously described. B. coli occurred in none of the male cases, but was the organism present in 6 out of 7 cases of bacilluria in women with enteric fever. The atypical bacilli appeared in the urine rather after the time for typhoid bacilluria, persisted for quite a short time, and appeared to cause no constitutional disturbance. Though practically unaffected by anti-typhoid serum they were agglutinated in varying degrees by the serum of the patient from which each was isolated. Having been stored on agar slopes at about 6° C. they were found, on re-examination a year later, to have acquired greater fermentative powers with regard to certain sugars. This property has usually been described as developing by continued growth and subculture of an organism in a solution of the sugar; but with these bacilli the power, though afterwards increased by subculture, developed in many instances spontaneously.

Dr. J. P. KINLOCH discussed the Excretion of Salt and Nitrogen in the Nephritis of Scarlet Fever and Diphtheria.

Dr. W. M. ELLIOTT spoke of the Wassermann Reaction in Children from the Poorer Classes. His investigation had aimed at ascertaining whether the wasted and unhealthy condition so often found in such children had *a syphilitic basis. Of 43 children who were ill-*nourished, pale, flabby, and sometimes with sores about the mouth or nose 6 gave a positive and 2 a probable positive reaction, though only 3 of the 8 showed signs of syphilis. Of 45 children who were apparently in good health 3 gave a positive and 1 a probable positive reaction, only one of the 4 showing signs of syphilis. Of 42 children who were well nourished but had nasal or aural discharge 5 gave a positive and 1 a probable positive reaction, and none showed any sign of syphilis. The conclusion drawn was that the proportion of cases in which the impairment of health was due to syphilis was small, and yet sufficiently large to indicate the desirability of applying the Wassermann test to such children with a view to treatment.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Exhibition of Cases.—Fatal Anæmia.—Fatality from Salvarsan.

A MEETING of this section was held on Jan. 30th, Dr. J. F. O'CARROLL, the President, being in the chair.

The PRESIDENT showed a boy, aged 16, who up to June last was in good health. Going to school in that month he got several wettings and sat in his wet clothes. In a week he noticed stiffness on rising from his seat. After about three months feebleness in walking ensued. There was not much to be seen in the lower limbs. The shoulder girdle muscles were considerably shrunk, and the wrist and fingers were stiff, but could be extended, though with pain. Muscular failure of the palm, thumb, and little finger. No defect in sensation. Almost all movements could be performed, but with diminished power. Slight palatal paralysis. The case suggested juvenile dystrophy, but there was nothing positive about it. The slight palatal paresis pointed to the possibility of more than mere primary muscular trouble.

Dr. G. PEACOCKE showed a man suffering from Anterior Poliomyelitis. He had been affected at the age of 45. The lower limbs were affected, and showed the various phenomena characteristic of the disease when fully developed.—Dr. ELLA WEBB and Dr. F. C. PURSER discussed the case.

Dr. PEACOCKE read notes of a case of Fatal Anæmia in a man aged 43. In February, 1913, he suffered from pain after food, vomiting, weakness, and anæmia, which almost entirely disappeared under treatment, but after a time returned. He came under observation in the following August, with vomiting, absence of HCl in stomach contents, obstinate constipation, great muscular weakness, feeble action of heart, dark pigmentation of skin of abdomen and chest, and severe anæmia of a secondary type. He gradually became weaker, and died on Dec. 2nd. Temperature was irregular, but never exceeded 100° F. No abdominal tumour; abdominal walls markedly rigid. Heart and lungs normal. Post-mortem examination revealed no evidence of disease. In the absence of malignant or adrenal disease, he asked, was this a case of pernicious anæmia?—Dr. G. E. NESBITT in view of the marked pigmentation would have expected to find Addison's disease.

Dr. NESBITT reported a fatality after 0·4 grm. salvarsan intravenously in a poorly developed man aged 25, the subject of syphilis, either congenital or acquired early in life. The injection was followed by two rigors, with symptoms of collapse, death ensuing in 25 hours. In the absence of signs of arsenical poisoning or other apparent cause of death, the theory of excessive liberation of toxin was advanced.—Dr. H. C. EARL, showing the pathological specimens, said the liver contained numerous gummata, large and small. Sections were shown under the microscope. The epiglottic mucous membrane was greatly thickened, but not ulcerated. The kidneys appeared normal, but much congested. The third, fourth, and fifth cervical vertebræ were necrosed. The laminæ were removed and the cord and dura mater seemed unaffected. The heart was healthy. The brain was not obtained.—Dr. G. E. P. MELDON said at the Lock Hospital a good number of cases were treated with salvarsan, many of the patients being in a shaky condition. The first point to attend to was thoroughly to clear *out the alimentary canal, otherwise the reaction would be* very much greater. In a doubtful case he thought it best first to put the patient on mercury and iodide, to destroy as many spirochætæ as possible, and thus lessen the reaction. In this case it was rather soon to expect arsenic poisoning; it must have been some vital process.—Dr. LILIENSTEIN (Germany) recalled the case of a patient aged 52, who died an hour after an injection of salvarsan. The patient showed evidence of marked arterio-sclerosis. Another patient developed complete parapleg after salvarsan and died from pneumonia.—Dr. W. D. O'KEL and Dr. HENRY MOORE discussed the case.—Dr. NESBITT, replying, was glad that in the opinion of the members blam did not attach to him for the administration of the drug this case. There was no loss of consciousness, paralysis, anything of that sort. There was no arterio-sclerosis.

Dr. LILIENSTEIN demonstrated to the section his Apparat for Producing Phlebostasis, and detailed its uses in cardia disease.

LEEDS AND WEST RIDING MEDICO-CHIRURGICA SOCIETY.—A meeting of this society was held on Jan. 30th Dr. T. Wardrop Griffith, the President, being in the chai —A discussion on Glycosuria was opened in a paper by Dr W. Hale White.[1]—Dr. W. H. Maxwell Telling stated tha the most important part of the problem of glycosuria was th treatment of the diabetic, for almost every glycosuria was a actual or potential diabetic. The present imperfect stat of our knowledge made this treatment incomplete an unsatisfactory, but he pointed out that one of the cause which contributed largely to this was the amount o time and trouble, and incidentally expense, involve in modern treatment. It was realised that there was n out and dried routine for these cases, but that each cas was a law unto himself. The most careful analyses an chemical investigations were required before the nitrogenou equilibrium and carbohydrate tolerance were determined and only then would a satisfactory diet scheme be formu lated.—Dr. P. J. Cammidge emphasised the importance o realising that glycosuria was a symptom due to a variety o causes and not a disease. The associated conditions varie therefore in different cases, and each case must be con sidered separately. In a majority of instances it was no possible to determine with certainty the underlying patho logical lesion, so that the treatment resolved itself int a question of how best to balance the food-supply agains the defective powers of metabolism of the particula patient. Most medical men in treating a case of glycos uria confined their attention too much to the presence o sugar in the urine and neglected other considerations which were equally, and in some instances more, important. An attempt should always be made to render the urine sugar-free, but it was even more essential that the patient should be put in nitrogenous equilibrium. So long as more nitrogen was being passed in the excreta than was taken in the food, *the patient could not improve*, even if his urine was free from sugar. The highly nitrogenous diet often *given* to diabetics was a relic of a past age, and certainly did a great deal of harm in many instances. As much care should be taken in determining the optimum protein intake as to the quantitative regulation of the carbohydrates of the diet. In both instances the problem could only be attacked satisfactorily by quantitative methods, by balancing the results of analysis of 24-hour collections of the urine against the nitrogen and sugar content of a series of test diet. In some cases it would be found that the tolerance of the patient for a particular kind or form of carbohydrate was much greater than for others, and that by administering this under suitable conditions a glycosuria which otherwise resisted treatment might be made to disappear. This was particularly the case when, as happened occasionally, the persistent sugar was levulose. It was obvious that the less the extent of the disturbances of metabolism the more readily would the conditions be controlled, and the easier would it be to adjust the diet so as to compensate for the defects that were present. The earlier treatment could be commenced the more satisfactory would be the result. Every case of glycosuria was a potential diabetic, and it was therefore unfair to a patient, no matter how slight an amount of sugar he might be passing in the urine, to treat it as a matter of little importance which could be dealt with by a rule-of-thumb method.—Dr. J. Le F. C. Burrow pointed out a few experimental facts with regard to the influence of ductless glands on diabetes.—The President, Dr. T. Churton, Mr. A. L. Whitehead, Dr. S. Samuel, and Dr. A. G. Barrs also took part in the discussion. —Dr. Carlton Oldfield showed two specimens of Dermoid Tumour which obstructed labour by blocking the pelvic cavity. 1. Primipara; very ill; uterus in tetanic contraction; child *in extremis*. Delivery by Cæsarean section. Tumour removed during puerperium. 2. Multipara; general condition of mother and child good. Removed tumour by abdomen after first withdrawing uterus through long incision. Labour progressed during suturing wound so that head was found in perineum at end of operation. Both mothers did well, and left the hospital with living children. —Dr. R. A. Veale showed a case of Wasting of the Peroneal and Quadriceps Muscles following a blow on the leg.—Mr. G. Constable Hayes showed: 1. A case with a history of Ulceration of the Soft Palate and Pharynx on and off for four years, during the whole of which period the patient was under mercury and potassium iodide. When seen three weeks ago the whole of the soft palate, and extending slightly on to the hard palate and pharynx, was one large granulomatous mass with a deep central fissure. After two injections of 0·6 grm. of salvarsan, at a week's interval, the whole mass was reduced to about half its original size. The pathological report (by Dr. M. J. Stewart) was as follows: "Wassermann reaction positive. The palatal lesion is essentially a plasma-cell infiltration of the subepithelial tissues, and these cells are present in enormous numbers. The epithelium itself, though thinned, is still intact, and there is no evidence either of tubercle or of new growth." 2. A case with no definite history of syphilis. Wassermann reaction strongly positive. Patient complained of complete nasal obstruction for 14 months. On examination there was marked hard thickening of the skin over the whole nose and also of the mucous membrane inside the anterior half of the nose. 0·6 grm. of salvarsan, given twice at weekly intervals, was followed by marked reduction of the swelling.—Dr. C. W. Vining showed a case of an Enlarged Spleen in a boy, with a negative blood picture and a trace of bile in the urine. The diagnosis lay between (1) splenic anæmia, (2) congenital lues, and (3) splenomegalic cirrhosis. The latter diagnosis was favoured owing to the presence of bile in the urine.—Mr. J. F. Dobson showed a case of Osteitis Deformans. The disease originated six years ago in an enlargement of the left tibia. Enlargements of other bones soon followed, and at the present time both tibiæ, both femora, the clavicle, sternum, spine, and cranial bones were extensively diseased. The patient had lost 4 st. in weight. There was no sign of the development of sarcoma.

---

[1] THE LANCET, Feb. 7th, 1914, p. 367.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this institution was held on Feb. 5th.—Mr. C. A. Adair Dighton read a short paper on Submucous Resection of the Nasal Septum. He considered that the operation should not be performed before the fifteenth to seventeenth year, nor where there was any evidence of active syphilis; he did not believe in a general anæsthetic, and he emphasised the fact that it was deviation in the upper portion of the septum which was serious.—Dr. H. Armstrong and Dr. J. Hay referred to the danger of employing adrenalin when the patient was under chloroform.—Mr. Arthur J. Evans described the removal of a sequestrum and involucrum from the upper arm of a child; within six months there was full functional recovery; no bone grafts were needed and no foreign bodies induced.—Mr. R. W. Murray referred to the tendency to suppurative pericarditis in cases of osteomyelitis. He related a case in which he had evacuated the pus from the pericardium, after which the boy recovered.—Mr. K. W. Monsarratt gave it as his opinion that as a general rule the diaphysis should not be removed.—Dr. McMurray emphasised the importance of the marrow when bone was implanted.—Mr. Simpson spoke and Mr. Evans replied.—Dr. Armstrong, in a short paper on Some Clinical Manifestations of Congenital Syphilis, introduced the subject with an expression of opinion that the type of the disease as now seen was decreasing in the severity of the symptoms, but that syphilitic disease of the central nervous system was increasing in frequency. The fulminating case of the infant who practically rotted away despite energetic treatment was becoming a rarity. Recent Wassermann statistics in children were reviewed, and owing to the complication and expense in blood, time, and money of this reaction the need of the perfection of Noguchi's "luetin" cuti-reaction emphasised. On the clinical side Dr. Armstrong did not regard "marasmus" in which there were no other signs of inherited lues as syphilitic in the true sense, though he thought there were probably cases in which marasmus resulted from the toxic effect of maternal syphilis upon the ovum without actual infection. Such cases would not respond to antisyphilitic treatment. On the question of the part played in the production of congenital deformities by syphilis the opinion was expressed, backed by clinical and Wassermann evidence, that though it was an undoubted factor in a number of cases it was not so in the majority, which had some other origin. Two rashes—pemphigus neonatorum and eczema seborrhoicum—sometimes mistaken for syphilitic lesions, were described and the diagnosis elucidated. Photographs of a case of "cauliflower" tumour of the anus, a papillomatous mass of the size of a large orange in a boy of 9, and of another patient a child of 8 months, with gangrene of the foot, diagnosed as a combination of Raynaud's disease and congenital syphilis, were thrown on the screen, and a case of paroxysmal hæmoglobinuria in a boy of 3 related. Other manifestations were touched on, and Dr. Armstrong concluded his paper with a review of the effects of inherited syphilis upon the nervous system. Syphilitic meningitis in children gave a clinical picture resembling that of the posterior basis of meningococcal type. The treatment differing so greatly lumbar puncture was essential early for diagnosis. Prognosis was fairly good, but blindness, deafness, and mental impairment were liable to follow permanently. Hemiplegia was often preceded by convulsions and frequently recurrent, the prognosis of functional recovery decreasing after each attack. Illustrative cases were quoted, including one of the fatal termination of untreated cerebral syphilis, death ensuing upon convulsions after the patient, a boy of 11, whose first symptoms dated from a hemiplegia at 7, had gradually become diplegic with extreme spasticity and imbecile.—The paper was fully discussed by Dr. E. W. Hope, Dr. F. H. Barendt, Professor J. M. Beattie, Dr. A. G. Gullan, Dr. C. J. Macalister, Mr. Murray, Dr. R. W. McKenna, Dr. W. B. Warrington, and Dr. Wilson.—Dr. Armstrong replied.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 4th, Dr. Donald, the President, being in the chair.—Mr. William Thorburn gave an address on "The Present Position of Cerebral Surgery." He began by stating that he intended to confine his remarks to the surgery of epilepsy and new growths of the brain—a branch of surgery that until quite recently did not admit of scientific review owing to the lack of statistics that covered any large numbers of cases. During the past year this absence of statistical basis had, as regards tumours, been filled in from various clinics, and in particular from the Queen-square Hospital. From his own statistics the number of successful cases of the surgical treatment of epilepsy worked out in round numbers at 25 per cent. The most satisfactory type of case was the traumatic, and the more definite the history of trauma the greater was the probability of cure. Idiopathic epilepsy was an extremely unsatisfactory condition for surgical treatment. The operation for epilepsy was a decompression necessarily and involved a craniectomy in all cases. Bony spiculæ when present were removed from the cortex; such cysts as were found were evacuated and their walls destroyed. These abnormalities, however, were not common. Adhesions between the brain and the dura, or between the dura and the cranium, were common; these were separated and strips of Cargile membrane interposed. Damaged cortex when present was removed. The bony defect in the cranium never caused any difficulty in the after-course of the case. The results obtained in Manchester, at Queen-square, and in von Eiselsberg's clinic were compared as regards the operative treatment of cerebral tumours. These results were by no means so depressing as they appeared at first sight from the published statistics. It must be remembered that many of these cases were moribund at the time of operation. In most the tumour was malignant, and anything in the nature of a radical removal was quite out of the question. The results of such operations should be judged only in comparison with the probable result in the case of a malignant tumour of the breast, in which the only course admissible was excision of the tumour nodule itself. An operation for a cerebral tumour should be approached from the standpoint of a decompression only, the growth being removed only when it was superficial and visible. Anything in the nature of exploring the brain substance should not be performed. It should be quite clearly understood that a complete cure could only be vicariously obtained. What was aimed at was the prolongation of life for a time, the lessening of the pain, and the relief of blindness. Judged from this standpoint, the operative treatment of cerebral tumours was rational and satisfactory. Exposure of the cerebral cortex was a procedure associated with little, if any, danger. Laceration of the brain substance, as must necessarily occur if the growth was sought for, was a dangerous and in most cases a useless proceeding. Operations for cerebellar tumours were in most cases unsatisfactory. In the case of cerebello-pontine growths there was a marked tendency, as the tumour developed, for the brain stem to become twisted, and this twisting being gradual was tolerated up to a certain point; removal of the growth or even simple decompression if performed in the usual manner resulted in the sudden release of this strain, a rapid "untwisting" of the brain stem, and, as a rule, rapid death from œdema or hæmorrhage into the bulb. In such growths the performance of decompression should be as gradual as possible, the operation being performed in three stages at least. At the close of his address Mr. Thorburn showed many specimens illustrative of his remarks.

OCKENDEN CONVALESCENT HOME.—At the annual meeting of the subscribers to the Ockenden Convalescent Home the report stated that 218 patients had been admitted during 1913, the average daily number of occupied beds was 19·2, and the average stay of each patient 31·20 days. The income was £762 and the expenditure amounted to £748.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, CITY-ROAD, E.C.—Sir Richard Biddulph Martin presided at the annual general meeting of this charity on Feb. 12th, when Mr. F. Swinford Edwards moved that the change of rule passed by the board on July 15th, 1913, "that a representative of the active surgical staff should in future have a place on the committee of management," be adopted as it was a most desirable reform. Such a member of the active staff knew by experience the daily surgical exigencies of the place. The resolution was carried without dissent. The report, which was adopted, made reference to the inevitable difficulties incidental to appealing for funds owing to the nature of the hospital. It also showed that during the past year the number of in-patients had been 621. The number of out-patients was 1854, who made a total of 6324 attendances.

Reviews and Notices of Books.

Surgical Experiences in South Africa, 1899-1900.

Being mainly a Clinical Study of the Nature and Effects of Injuries produced by Bullets of Small Calibre. By GEORGE HENRY MAKINS, C.B., F.R.C.S. Eng., Senior Surgeon to St. Thomas's Hospital; Vice-President of the Royal College of Surgeons of England, &c. Second edition. Illustrated. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 504. Price 10s. 6d. net.

THE first edition of this well-known work was published in 1901.[1] For some years it has been out of print, and its reappearance will be welcomed. It is practically a reprint of the former issue, except for the continuation of the histories of some of the cases, especially those of aneurysm. In bringing this volume to the notice of our readers we need say little by way of introduction; its extremely practical character, based entirely on experience, the admirable clearness with which it is written, and the large number of illustrations (28 full-page plates and 105 figures in the text) constitute its value.

There is no need to revive the old controversy that raged as to the efficiency of military medical administration in the South African war; accusations often retain their vitality long after they have been satisfactorily refuted; but the testimony of the leaders of the profession who took part in that war has been practically unanimous as to the efficiency of the medical aid rendered, taking the campaign as a whole. Mr. Makins speaks for the excellence of the organisation of the General Hospitals and the success of their surgical results; he recognises the immense strain that was thrown on the medical service of the army during the campaign, and considers that "the medical profession may well be proud of the efforts made by its military representatives to do the best possible work under the circumstances." The aseptic nature of wounds by small bullets of high velocity (due to renewal of the bullet's surface by passage through the barrel and to the heat to which it has been subjected), and, on the other hand, the invariable suppuration of shell wounds (with the exception of clean leaden shrapnel tracks), are two important generalisations now universally acknowledged. Gunshot wounds of joints, formerly causing the greatest anxiety to the surgeon, are now little more to be dreaded than uncomplicated wounds of the soft parts alone, "owing to the harmless character of the projectile [the small calibre bullet] as a possible infecting agent."

Radium: its Physics and Therapeutics.

By DAWSON F. D. TURNER, M.D. Edin., F.R.C.P. Edin., Medical Officer in charge of the Radium Department, Edinburgh Royal Infirmary. Second edition. London: Baillière, Tindall, and Cox. 1914. Pp. 170. Price 5s. net.

IT was our pleasure to review the first edition of this handy volume (THE LANCET, April 1st, 1911), and that a second edition of a work on such a highly specialised subject should so soon be called for is evidence of the popularity it has been accorded.

In the present edition we have all the good points of the first one, and a lot of new matter is added so as to keep in step with the latest ideas on the physical properties and applications of radium in the treatment of disease. As an example, a new chapter has been added on the use of the emanation of radium and thorium compounds; also the section dealing with the treatment of malignant disease has been considerably extended, and the details of many new cases have been added. While some progress has been made in this direction, especially in localised lesions, the fact still remains that we are not much further forward as regards inoperable cases.

---

[1] THE LANCET, June 1st, 1901, p. 1544.

This is a valuable handbook on radium, and is to be recommended to those who wish to keep in touch with present ideas.

The Principles and Practice of Gynæcology for Students and Practitioners.

By E. C. DUDLEY, A.M., M.D., Professor of Gynæcology, North-Western University Medical School. Sixth revised edition. Illustrated. London: Henry Kimpton. 1913. Pp. 795. Price 25*s.* net.

SOME five years have elapsed since the last edition of this book appeared. A large part of it has been rewritten, more particularly the chapters dealing with general principles, inflammation, tumours, and traumatisms. The subjects are arranged in pathological and etiological sequence, so that, for example, infections and inflammations are brought together, and tumours are treated in one part, traumatism in another, and displacements in another.

It is always interesting to note what view any author takes of such new theories or methods of treatment as have appeared since the last edition of his book was published. In this edition we find that Professor Dudley has not seen any reason to change his views on the merits of the extended abdominal operation in the treatment of operable cancer of the cervix. He is still inclined to regard ignihysterectomy—a combined vaginal and abdominal hysterectomy carried out mainly by the cautery—as a better operation than that commonly known by the name of Wertheim. His readers must, however, bear in mind that some surgeons at any rate make a great use of the cautery knife in performing the extended abdominal operation, and no doubt it presents many advantages. At the same time it is interesting to note that the author is not convinced of the greater advantages presented by Wertheim's operation. Professor Dudley is essentially conservative in his opinions. For example, in mentioning the use of X rays in the treatment of cases of fibromyomata of the uterus he recalls the lessons of the use of electrolysis in such cases, and is evidently very incredulous of the results said to have been obtained; and yet every day brings fresh evidence of the great value that this method presents in the treatment of fibroid tumours of the uterus. It is surprising to find in a book of this scope the subject of ovarian pregnancy dismissed in one line, as well as so inadequate an account of the pathological changes which occur in the tube in connexion with tubal pregnancy.

The book has many good features, and is strongest in its descriptions of the various forms of plastic operations upon the pelvic organs; indeed, in this respect it would be difficult to surpass it. At the same time, in our opinion, an undue amount of space is devoted to these and kindred subjects to the detriment of the rest of the work.

A Handbook of Hygiene.

By A. M. DAVIES, M.R.C.S. Eng., L.S.A., D.P.H. Camb., Lieutenant-Colonel, R.A.M.C. (retired), late Professor of Hygiene, Royal Army Medical College. Fourth edition, revised and enlarged by A. M. DAVIES and C. H. MELVILLE, M.B., C.M. Edin., D.P.H. R.C.P.S. Lond., Brevet-Colonel, R.A.M.C., late Professor of Hygiene, Royal Army Medical College. London: Charles Griffin and Co., Limited. 1913. Pp. 718. Price 10*s.* 6*d.* net.

HYGIENE nowadays includes such a number of subjects that a book with that title invariably means an inconveniently large volume. When, for example, we consider that an adequate treatment of the subject must include, as does the volume before us, discussions upon air and ventilation, water and water-supply, food and dieting, the removal and disposal of sewage, clothing, habitations, personal hygiene, soils and sites, climate and meteorology, the causation and prevention of disease, and disinfection, we realise that considerable difficulty must be found in providing room for the materials within the bounds of a "handbook." Each of these questions well may claim a separate work to itself, but apart from those who want special monographs there is a large *clientèle* requiring the presentation of broad essentials in one volume. In reality, the departmental developments of hygienic questions have been so great as to render impossible an account of the subject complete in a single volume. That is our one criticism of this excellent compilation.

As new editions of standard works are brought out we find that the writers are compelled to omit those former special chapters which dealt with technical details. It would be futile, for instance, to attempt to include now even a *résumé* of the bacteriological refinements which are day by day added to the armamentarium of the bacteriologist in connexion with his methods of examination of foods, water-supplies, and sewage effluents. Nor similarly can it be pretended that a useful account can be given of the latest developments of analytical work applied to the analysis of air, water, and food, without trespassing upon much space which is better occupied with general considerations. These are special departments the importance of which in their bearing upon sanitary science can be instructively indicated, but description of the technique is left to the special volumes. Such appears to us to be the lines upon which a modern text-book on hygiene should be founded, and we welcome the fourth edition of this work because, in our view, it fulfils this definition. Considerations of space have rendered necessary the suppression of the sections on the "Analysis of Air, Water, Food, &c.," and in many other directions prudent omissions have been made. Yet there is retained a most instructive account of general principles written with an observance of modern advances.

The sincerity of the writer's aim, declared in the first edition to be "to digest the information into as small a compass as seemed advisable without sacrificing clearness, and at the same time omit nothing of real importance," receives proof in the care which he and his coadjutor have bestowed upon the revision of the new edition, and in the judicial selection of essential materials.

In regard to the reference to the work of THE LANCET Commission upon disinfectants in the chapter on Disinfection, we should point out that Professor G. Sims Woodhead was responsible for the bacteriological portion of the inquiry only, and therefore the statement is not correct that (p. 679) "Woodhead also made some chemical investigations as to the actual content in phenol or phenoloids of the different patent preparations on the market, and found that it was possible to arrive at some idea of the disinfectant power of such compounds by these means." As stated in the report, the chemical part of the inquiry was undertaken by Mr. S. A. Vasey, of THE LANCET laboratory, and Mr. J. E. Purvis, of the University Chemical Laboratory, Cambridge.

Spätpsychosen Katatoner Art.

Eine Klinische Studie von Dr. med. Maurycy Urstein, Warsaw. Berlin and Vienna: Urban und Schwarzenberg. 1913. Pp. 440. Price, paper, 16 marks; bound, 18 marks.

In this monograph Dr. Urstein has described with minutest detail the cases of some 40 patients suffering from varieties of psychosis developing after the age of 40. He finds certain resemblances in all psychoses which make their appearance in the later years of life, whatever be the underlying pathological process or the actual nature of the disease. He directs attention, however, mainly to the group in which the psychosis approximates to the type of catatonia. There are chapters on the influence of the climacteric on the psyche, on the relations between the time of life and the symptomatological type of the psychosis with which an individual may be afflicted, and on the physiology and psychology of old age.

The book is of value chiefly from the documentary viewpoint; the cases are elaborated with a wealth of clinical description that could not be improved on.

Mind and Health: with an Examination of Some Systems of Divine Healing.

By Edward E. Weaver, Ph.D., sometime Fellow in Clark University. With an Introduction by G. Stanley Hall, Ph.D., LL.D., President of Clark University. New York: The Macmillan Company. 1913. Pp. 500. Price 8*s*. 6*d*. net.

Of making of books on psychotherapy there is no end. It is a legitimate assumption that there is a demand for them, but whether they are intended for the medical profession or for the lay reader, intelligent or otherwise, is not always easy to determine. The terminology of not a few cannot be properly understood, in our opinion, by any but the professed psychologist or physician, yet it not infrequently happens that such books also contain matter couched in language so popular that the impression abides with the medical reader that the volume is not for him. In the preface to the present work we read that "it is especially offered to those, on the one hand, who maintain an exclusive religious healing, and to those, on the other hand, who disdain religious healing of every kind."

The standpoint of the book is frankly the Christian standpoint; and the general outlook is that the time has come for minister of religion, physician, psychotherapist, faith healer, and social worker to put away suspicions of each other's work, to join efforts, and to establish that therapy which will best promote the highest efficiency of the worker for the Kingdom of God. We fully appreciate the reverent spirit that pervades the book, the tolerant atmosphere in which the reader finds himself, and we acknowledge the truth and practical importance of many of its main principles. But with the author's plea for a religious psychotherapy we do not find ourselves in complete agreement, and no coöperation such as the author foreshadows can ever be possible till a common working basis is reached. How that basis can be reached when religious tenets and opinions are as widely divergent to-day as ever they were it is difficult to see. Moreover, while we do not hold that science and religion are inherently antagonistic, a rational psychotherapy must be a scientific psychotherapy, and the tendency of the religious psychotherapist, either from ignorance of medicine or from his particular habit of interpretation, to claim for his religion results which are capable of other explanations is not calculated to further that coöperation for which the author hopes. No physician but rejoices when cures are effected, by whatever method attained; yet the risk of mistake in diagnosis is fully appreciated only by the physician, and we strongly insist that no form of treatment can relegate the importance of complete and painstaking medical examination to the background.

The present volume is characteristic of a certain type of book-making that lends itself to criticism. It is simply packed full of quotations, often pages at a time, from all sorts of writers, mostly American, and it may be said that many of these quotations are noteworthy both for the wordiness and superficiality of thought which they reveal. The author's own contributions to the book are not always couched in intelligible phraseology; for an instance, the following passage, one of many, may be quoted: "The non-personal, non-synthetised experience, that yet achieves some registry in the nervous system, which under special conditions becomes observable as furnishing mental nourishment to a subconscious form of assimilation, is thus the dissociated experience; and the consequences to the intelligence in which such states habitually occur and multiply inevitably affect the entire personal integrity of consciousness." The book contains many loosely constructed sentences cast in language that is nebulous to a degree, effectively concealing what thought may lie behind; the frequent employment of terms in other than their accepted usage, so characteristic of a certain number of American writers, is one against which a protest must again be entered.

Practical Guide to Diseases of the Throat, Nose, and Ear, for Senior Students and Junior Practitioners.

By William Lamb, M.D. Edin. Third edition. London: Baillière, Tindall, and Cox. 1913. Pp. 352. Price 7*s*. 6*d*. net.

There are many senior students and junior practitioners to whom this new edition of Dr. William Lamb's "Practical Guide to Diseases of the Throat, Nose, and Ear" will appeal, because the author has spared no pains to make the book worthy of its title—a really helpful "guide" to the beginner in the study of these diseases. Whilst the original character of the manual has not been changed, the subject matter has been revised and brought up to date as far as that is possible in an elementary work on a very progressive special department of practice. Several short sections have been added on various practical points, such as oral sepsis, which is still very generally left out of account as a possible cause of disease. Attention is drawn to the risks at times attending the tonsil and adenoid operation. The relative merits of tonsillectomy and tonsillotomy are discussed. To the part dealing with diseases of the ear a section has been added on the danger signs in ear disease, the importance of which it would be difficult to overstate. Whilst adding new matter the author has not overloaded his pages with information which the student can easily find in any work of reference. The pages have been given up to practical matters, and more particularly to difficulties which the beginner is sure to encounter, and which sometimes receive but scanty notice in systematic works.

LIBRARY TABLE.

Burdett's Hospitals and Charities: the Year Book of Philanthropy and Hospital Annual. London: The Scientific Press, Limited. 1914. Pp. 1055. Price 10*s.* 6*d.*—For many years an effort has been made by Sir Henry Burdett to expedite the date of publication and issue this book to his subscribers, so as to bring it out not later than the first week in February of each year. Hitherto this has been found to be impossible of accomplishment, but with the celebration of the silver jubilee of the publication the editor has succeeded in attaining his aim. Only those who have any experience in compiling publications, the information for which is obtained by letters and schedules from a large number of sources, can appreciate the difficulties with which the editor of a publication like Burdett's Charities has to contend, even though he receives, as no doubt has been the experience here, the hearty coöperation of the persons to whom he applies for assistance. We congratulate Sir Henry Burdett, therefore, on having at last attained the ideal which he has so consistently aimed at. We regret, however, to note that in his preface he tells us that he feels, by reason of his age, that the time has now come when he must relinquish his task, and he expresses the hope that some competent person having a keen interest in the voluntary system of hospitals will come forward and coöperate in the compilation of future volumes, although no remuneration attaches to the office. The work is now so well known and widely used that it is almost unnecessary to describe it beyond quoting the title-page, which describes the book as containing a review of the position and requirements, and chapters on the management, revenue and cost of the charities, an exhaustive record of hospital work for the year, and as a trustworthy guide to British, American, and colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, consumption sanatoriums, religious and benevolent institutions and dispensaries. In the current volume will be found the latest figures from the audited statement of accounts of some 6000 separate institutions for the period ending Dec. 31st, 1912, and there are special chapters dealing with almost every phase of medicine and nursing from the point of view of charity. It is a review of all matters affecting the progress and work of organised charities of every description throughout the English-speaking world, and the complete 25 volumes constitute an encyclopædia of the history and progressive development of voluntary medical charity.

Gould and Pyle's Pocket Cyclopædia of Medicine and Surgery. Second edition. Revised, enlarged, and edited by R. J. E. Scott, M.A., B.C.L., M.D. New York. London: H. K. Lewis. 1913. Pp. 732. Price 5*s.* net.—This little book aims to fulfil in regard to the subject matter of general medicine the purpose of rapid reference that the corresponding medical dictionaries fulfil in regard to medical nomenclature. As Gould and Pyle's "Cyclopædia of Practical Medicine," on which the first edition of this work was based, has been recently edited and brought up to date by Dr. Scott, it was deemed advisable to entrust to the same editor the revision of the present work. While there is much that is of value and convenience in the book, we have been unable to find any references under coccus, micrococcus or their specific names, to pneumococcus, gonococcus, staphylococcus, streptococcus, diplococcus, or the causative bacteria or bacilli of various diseases, nor are they mentioned, though pictures of staphylococci, streptococci, and diplococci are given, under bacteriology. The term plasmodium malariæ is not to be found, even under malaria. Trypanosoma and trypanosomiasis and uncinariasis are not given, and even under hookworm disease the microorganism is referred to only as the hookworm, uncinaria not being named. Ankylostoma, however, has a place. Treponema and spirochæte also find no place, except under syphilis. Stegomyia is not named, even under yellow fever, nor are tsetsefly and anopheles. Of diseases, kala-azar and tick fever do not appear, and we have found no reference whatever to bacterio-therapy, vaccine-therapy, inoculation therapy, or the opsonic index, to radium or radium therapy, to the cardiograph, hæmatometer, or sphygmomanometer, though catheter and cautery find a place. Under thiosinamine the most useful function claimed for it by some of causing resorption of fibrotic deposits has no mention. There are serviceable tables of arteries, bones, muscles, nerves, tumours, and urinary sediments, to which one of operations would be a sound addition. From the partial list of modern subjects with regard to which we have looked in vain for a reference, we feel bound to consider that, useful as the book might be made, it can hardly be regarded as up to date. It strikes us as a valuable idea inadequately carried out.

Hysterie: Zur Frage über die Entstehung Hysterischer Symptome. By Dr. J. M. Raimist, Leiter der Nervenabteilung des judischen Hospitals in Odessa. Berlin: S. Karger. 1913. Pp. 101. Price 3.50 marks. —In this brochure Dr. Raimist is concerned with an endeavour to establish a relationship between the type of hysterical symptoms in any given case and the nature of the exciting factors precipitating the hysteria. In many instances, the clinical details of which are given, he can demonstrate a logical, intellectual relation of cause and effect between the trauma, using the word in its widest sense, and the symptoms. In others, he can trace no such connexion, and is forced to conclude that the exteriorisation of an emotional shock may follow lines that could not be foreseen; and conversely, that from the type of symptoms the original psychical lesion cannot always be determined. The author does well to draw attention to the as yet incompletely solved question of the forms which the expression of a psychical trauma may assume.

Research Studies in Psoriasis. Reprinted from the *Journal of Cutaneous Diseases, including Syphilis,* of October and November, 1913. By Jay F. Schamberg, M.D., John A. Kolmer, M.D., A. I. Ringer, M.D., and G. W. Raiziss, Ph.D. New York: Rebman Company. Pp. 140.—These pages record an exhaustive study of the nature of psoriasis.

New Inventions.

A NEW DRAINAGE-TUBE INTRODUCER.

THE drainage-tube introducer, here illustrated in its two forms, is referred to in my paper read on Feb. 10th before the Surgical Section of the Royal Society of Medicine, entitled "On the Most Efficient Method of Drainage in Septic Peritonitis."[1] It is intended for rectal, vaginal, or loin drainage. The drainage-tube introducer is in the shape of a well-known form of periosteal elevator, with one end slightly curved, terminating in a blunt point, for perforation from within out of the bowel, vaginal posterior cul-de-sac, or the loins, in the case of the routine subphrenic drainage recommended in all cases of septic peritonitis, and as a preventive of this in immediate suture of gastric or duodenal ulcers, &c. The other extremity of the instrument is bulbous, with a depression between the bulb and stem. A good-sized drainage-tube, No. 16, red rubber tubing, of ½ inch external bore and 5/16 inch internal bore, corresponding with the cylindrical shank of the instrument (but which can be less than this if desired), is fitted over the bulbous end, which has a thread on it to prevent the tube slipping off. The free edge of the tubing lies in the depression beyond the bulb, so that no obstruction or resistance is perceived in introducing it from within out through any structure — e.g., the bowel, vagina, or abdominal wall. For further details of its use the reader is referred to the text of the riginal paper when published in the *Transactions of the Royal Society of Medicine.*

FIG. 1.

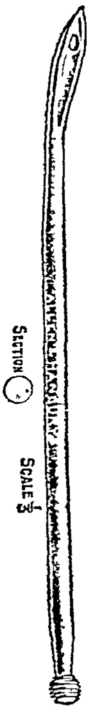

FIG. 2.

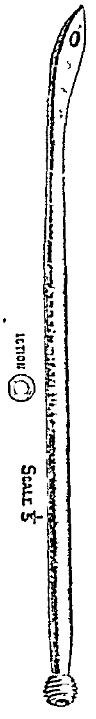
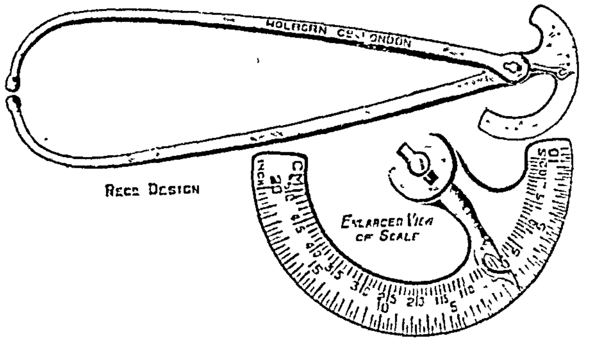


The drainage-tube introducer, which has been very tisfactorily manufactured according to my designs by Messrs. Allen and Hanburys, Wigmore-street, London, W., s 9¾ inches long, the diameter of the cylindrical shaft being ½ inch. Fig. 1 represents the ordinary form of the nstrument. Fig. 2 is another form, with hollow shank for ccessory employment in emergencies as an irrigator. In both forms of instrument there is a large eyelet, permitting of its use as a serviceable pedicle-needle, if desired. From ts general form, the drainage-tube introducer can also be employed as a periosteal elevator. The inconvenience and expense of a multiplicity of instruments has thus, to some extent, been met in this addition to the surgeon's armamentarium by giving to the new weapon multifarious uses.

Harley-street, W. HENRY CURTIS, F.R.C.S. Eng.

AN IMPROVED PELVIMETER.

THERE is much valuable information to be gained in the regular use of a good pelvimeter in obstetrical practice. Certain complications of labour may be foreseen by employing his diagnostic aid, and be dealt with intelligently. The French type of pelvimeter has these advantages over other orms: simplicity, lightness, compactness, and ease of manipulation. It is adaptable to all the external measurements in common use, and the principal internal ones also. Dr. T. M. Eden has strongly recommended it. However, its usefulness has been limited by the unfortunate lack of agreement regarding a standard scale, some obstetricians using the English, others the French system. In order to extend the scope of this pelvimeter I have modified and improved it so as to include both metric and English scales, and have added to its simplicity by the removal of several ornamental grooves. The complete instrument now consists of but two parts which are readily cleaned. The scales are very easy to read. The apparatus needs but a single investigator. A new and important use has been included and should be of great service to any person collecting a series of obstetrical measurements from many sources, and wishing to put all of them in the same scale; for by simply placing the indicator at the figure given the conversion into the other scale may at once be read off without appreciable effort or calculation. The recent excellent article by Dr. Daniel Dougal in the November issue of the *Journal of Obstetrics and Gynæcology* further emphasises the value of the information gained by the routine use of the pelvimeter in obstetrical cases. The initial cost of the instrument I have designed is small, and I hope many will be induced to use this instrument of precision, and so learn ascertainable facts, thus placing obstetrics a degree nearer to being an exact science.



The instrument has been made to my designs by, and may be had from, The Holborn Surgical Instrument Company, 26, Thavies Inn, Holborn-circus, London, E.C.

Toronto, Canada. GORDON GROTE COPELAND, B.A., M.B.

OPENING OF THE CLINICAL LABORATORY, ADDENBROOKE'S HOSPITAL.—On Feb. 13th the new clinical laboratory, founded by Mrs. Bonnett in memory of her son, the late John Bonnett, was formally opened. This laboratory will be a valuable addition to the resources of the hospital, which up to the present time has been dependent on the university authorities, who have allowed the clinical investigation work of the hospital to be carried out in the medical schools. The proceedings began with a luncheon in the dining-hall of Downing College. The Master, Professor F. Howard Marsh, was in the chair, and about 50 members of the Cambridge Medical Society were present. The Master, in proposing the toast of Mrs. Bonnett's health and the memory of John Bonnett, referred to the long period of service John Bonnett had given to the hospital, to his estimable qualities, and to the generosity of his mother in building and endowing a clinical laboratory to keep his memory alive. Dr. Walter Malden responded on behalf of Mrs. Bonnett. An adjournment was then made to the laboratory, which is situated at the north end of the hospital. It consists on the ground floor of a cold storage mortuary with freezing plant, a post-mortem room, a mortuary chapel, and a waiting-room for friends. A doorway on the right cuts off the laboratory from the mortuary. The laboratory comprises a dark room for photography and spectroscope work, a chemical laboratory, and a room for sterilising and washing up. Upstairs there is a small storeroom, a room for histology, and a large bacteriological laboratory. Sir Clifford Allbutt, Regius Professor of Physic, in declaring the laboratory open, remarked that such institutions were a necessary part of a modern hospital, and related his early endeavours to get such a laboratory started. He dwelt on the necessity for a close connexion between pathological investigation and the clinical work in the wards, and the danger of the study of pathology becoming too academic if divorced from the wards. Professor Sims Woodhead, endorsing Sir Clifford Allbutt's remarks, emphasised the value of the addition to the resources of the hospital which had been provided by Mrs. Bonnett's generosity.

[1] See summary on p. 533 of present issue.

HOMMEL'S HÆMATOGEN

Entirely Free from Antiseptics.

Contains purified Hæmoglobin 80%, Glycerin 20%, and a trace of aromatic flavouring.

A PURE SOLUTION of OXYHÆMOGLOBIN containing all the valuable albuminous substances (proteids) present in the blood of the living body, and iron in a state of organic combination.

A POWERFUL RESTORATIVE in ANÆMIA, TUBERCULOSIS, and many diseases dependent on a defective condition of the blood.

EASILY DIGESTED. Creates an appetite for other food.

PALATABLE, NUTRITIOUS, and free from any constipating tendency. May therefore be given regularly to DELICATE CHILDREN and AGED PERSONS.

☞ SPECIALLY ADAPTED on account of its efficiency and comparative cheapness for use in SANATORIUMS, and for dispensing UNDER THE INSURANCE ACT.

In prescribing please always specify HOMMEL'S Hæmatogen.

Samples Free and Carriage Paid on application to—

HOMMEL'S HÆMATOGEN, 36/36a, St. Andrew's Hill, Doctors' Commons, LONDON, E.C.

THE TERRITORIAL MEDICAL SERVICE.
By a Special Correspondent of THE LANCET.
WITH PREFACE BY SIR ALFRED H. KEOGH, K.C.B.,
DIRECTOR GENERAL, ARMY MEDICAL SERVICE.

[illegible]

TO ADVERTISERS.

The Manager begs to intimate that in order to meet, to some extent, the demand made by Advertisers for "position" pages—in which respect THE LANCET *will still continue to be deficient as compared with most weekly Journals—the position occupied by this and the following page has been created, and will be known as "Preceding Leader."*

Heavy types or heavy blocks will not be eligible for this position, nor can any border rules be used.

The price will be £12 net per page and pro rata, with a minimum space of one-eighth of a column (=1⅛ in., 15/-), and proceeding by one-eighths (the usual two columns to a page), and consequently there will not be any serial discount.

It will not be practicable to accept any conditions calling for space on either page in particular, or for any precise position on the page, and successive weekly insertions cannot be guaranteed.

laid down. As Mr. HEY GROVES says, "the most conservative surgeon would not allow a fractured patella with much displacement to go unsutured, nor would the most ardent advocate of operations suggest an open attack upon a subperiosteal fracture of the fibula without displacement." This example is given to show that in some cases operative interference has little risk and yields such admirable results that it must be employed; and that in other cases the results are so good without operative interference that such measures would be undreamt of. But this is not the only way in which the necessity of treating every case on its own merits can be indicated. It is perfectly easy to see that in some subjects an operation which is not entirely necessary had better be avoided for general reasons, and that at other times the accident may occur in an excellent subject for operation, but in an environment where the special treatment cannot be provided by a surgeon familiar with a difficult and anxious technique. There is no general answer to the question whether the non-operative or operative treatment of fractures is the better, but the valuable work that is being done will help us enormously to clear up our doubts. It must be borne in mind that it is not the cosmetic appearance of the bone, as shown by a skiagram, that really counts in the consideration of the question of the success of the treatment of a fracture, but the functional value of the limb afterwards; and the Roentgen rays have shown us clearly that perfect functional results may accompany the healing of a fracture where there is no small degree of anatomical deformity. Yet the more nearly the surgeon attains to a perfect anatomical result the more likely is the functional result to be perfect also; so that there can be no doubt that the surgeon should do his utmost to obtain as exact a reduction of the fragments as can be. When he is convinced that he cannot by other means replace the fragments the question of recourse to operative procedures arises. Undoubtedly different surgeons will judge differently as to the urgency of individual cases, but nearly all surgeons are now much more ready to operate in fractures than they were even a few years ago.

◆

Bertillonage.

M. ALPHONSE BERTILLON, the great worker in anthropometry, has died at the age of 61. He had been an invalid for many years, and some time ago underwent transfusion, for which his brother, Dr. JACQUES BERTILLON, the director of the Bureau of Sanitary Statistics of the city of Paris, furnished the blood. The beneficial result was, however, only temporary. ALPHONSE BERTILLON was a son of Dr. LOUIS ADOLPHE BERTILLON, one of the founders of the School and the Society of Anthropology at Paris. He began his career by researches in ethnography, his first book being entitled "L'Ethnographie Moderne des Races Sauvages." It was in relation to this that he worked out his accurate method of mensuration of the various parts of the human body and elaborated a mode of classification of these documents which gave rise to the establishment of the anthropometric records (*fiches*) of identity of criminals, a department created at the prefecture of police in Paris in 1880. M. BERTILLON never ceased to add to the completeness of his method by the addition of new signs, and particularly by the adoption of the examination of finger prints, a method borrowed from the Chinese, and elaborated in this country by the late Sir FRANCIS GALTON, Mr. H. FAULDS, and Dr. J. G. GARSON. By his anthropometric studies, though he was not a medical man, M. BERTILLON allied himself to medicine.

M. BERTILLON'S method is often spoken of as though it relied for its efficacy on dactylography. In point of fact, "Bertillonage," as it has been termed, depends on the application to the bones of man of two principles comparable to those which form the basis of the method of identification by means of imprints of the papillary ridges on the fingers. These principles are: (1) that no two skeletons are ever identical in their measurements; and (2) that certain bone measurements remain the same through life. Starting from these principles M. BERTILLON divided the population of the world into 243 classes, which together represent every possible combination of the following five sets of bone measurements: (1) length of head; (2) breadth of head; (3) length of middle finger; (4) length of left foot; (5) length of forearm from the olecranon to the extremity of the middle finger. Each of these classes was again divided into three subclasses by arbitrary limits representing measurements respectively average, above the average, and below the average. The arbitrary figures by which M. BERTILLON defined the limits of his average term in bone measurements could not have been arrived at save as the result of immense toil and experience. The method, after its enthusiastic introduction by the French criminal department, was adopted more or less universally among the civilised nations. It will be remembered that in 1894 the present PREMIER, then Secretary of State for the Home Department, appointed a committee to inquire into the value of the anthropometric method of identifying criminals, with the result that the Commissioners accepted it in the main, combining it, however, with GALTON'S system of identification by finger prints, founded on the fact that the patterns on the papillary ridges of the tips of the fingers and thumbs are persistent throughout life and show in every individual an infinite variety of design.

The essential difference in operation between BERTILLON'S anthropometry and GALTON'S finger-tip identification lies in the fact that the finger imprints can be taken by any person of average intelligence, but require a highly skilled person to interpret them. Anthropometric measurements, on the contrary, have proved to be very difficult to secure with accuracy, even with perfect instruments, but are comparatively easy of interpretation. After some years of testing, consequently, "Bertillonage" was in 1900 finally dropped in Great Britain, the chief causes of its supersession being the costliness and liability to derangement of the necessary instruments, the necessity for expert measurers to use them, and the frequency with which, in spite of the greatest care, errors of measurement were found to occur. Since experts must be employed with either system, it was found better to retain a few at headquarters to interpret the records of dactylography, which can be taken anywhere by persons of average intelligence and forwarded for interpretation, than to supply the services of the experts all over the land to obtain osteological data, even though, when taken, they are comparatively easy of recognition.

The Control of Measles.

AT the meeting of the Medical Officers of Schools Association in May last Dr. JAMES KERR initiated a valuable discussion on the Control of Measles. Dr. KERR'S address has now been printed,[1] together with the discussion, and the pamphlet forms a comprehensive survey of the problem as it affects this country. It seems to be agreed that "control," in the sense in which it can be applied to scarlet fever, is impracticable. Public health measures, therefore, of the routine type associated with other infectious diseases are not likely to prove of much service. And it is to this fact that we look for the explanation of the complaint that notification is said to be of little value. Notification *per se* does not help us as much with measles because of the well-known fact that measles is most infectious prior to the appearance of the rash and before anything but a guess can be made as to the nature of the illness. But, as has been pointed out by Dr. C. J. THOMAS and other observers, a knowledge of the existence of cases of the disease can be of the greatest possible value if it leads at once to the medical supervision of each case. By proper medical care the mortality and evil sequelæ of measles may be reduced to a minimum, as is well brought out in the figures below contrasting the measles mortality in Aberdeen, where there is no organised effort to combat the disease, with the position in Willesden, where Dr. WILLIAM BUTLER, the medical officer of health, has made strenuous efforts in this direction. In the age-period 1 to 2 years the case mortality in Aberdeen is precisely double that in Willesden, and while in the age-periods from 2 to 3 and 3 to 4 the figures nearly approximate, the advantage is always with Willesden. During the first year the case mortality in Aberdeen is 13·9 against 2·8 in Willesden; and over the whole of the first four years the ratio is 6·5 in Aberdeen against 3·0 in Willesden. Much the same proportion exists in the fourth year of life, while, from 5 years and upwards the case mortality is 0·5 in Aberdeen, against 0·3 in Willesden.

How a knowledge of the presence of measles cases should be obtained is another question, but it is significant that Dr. BUTLER, being medical officer to the Education Committee at Willesden, was entirely dependent on notifications coming from the schools. Dr. THOMAS, on the result of whose five years' investigation of measles in Woolwich the present regulations of the London County Council with respect to this disease are based, spoke strongly against school closure, one important reason against this procedure being that it deprives us of a knowledge of the incidence of the disease, and hence lessens our power of helping to combat the disease. A glance at the chart, illustrating Dr. KERR'S paper, of the crude death-rates for measles, scarlet fever, and diphtheria in London since 1885 shows a fall in the last two illnesses and a lesser fall in measles. This is no doubt largely due to improved hygiene, though the possibility of a change of type in disease is recognised by public health authorities; but in the case of measles the fall is markedly less than the fall in the other two diseases. Nevertheless, it seems agreed that the chief hope of combating measles lies in what Dr. KERR calls "improvements in regard to habits of life, housing, and space to live." Incidentally a strong protest should be entered against the bad hygienic conditions in which measles is nursed in many of the public schools. The relatively harmless character of the disease among better-off children shows this point clearly, and some who contributed to the discussion were of opinion that social condition was much more important than age as affecting the gravity of measles. To escape measles altogether seems chimerical, and many speakers were against the effort unduly to postpone the disease. Dr. KERR allows that it would probably not be a loss in the public health sense if all children could pass through measles by the age of seven; but the awkward thing is that the case mortality is terribly high in infancy—a fact which makes it clear that postponement of the attack is of the greatest possible value.

The education of parents in regard to methods of treatment of measles, an adequate medical treatment of all cases, including a more scientific and aseptic treatment, and hospital isolation for severe cases, are obvious proposals to meet the situation. Notification, whether from school, parent, or doctor, is useful only if it serves to act as the alarm bell calling up medical help in treatment. Dr. C. E. SHELLY, in summing up the discussion, suggested that we might obtain other useful hints by pushing our clinical observations further, asking incidentally, what is the pathology of Koplik's spots? If investigation along the indicated lines gave us some means of making an early diagnosis the [illegible] would be simplified. But in view [illegible] it appears beyond our about a preparation which shall stimulate the protective cells is that the toxins contained in it should be less virulent than those of the actual bacilli causing the disease, and that their molecules should be more easily acted upon and destroyed. Professor Béraneck has carried out experiments on guinea-pigs, which he states are the "animals of choice" for the study of tuberculosis—a view which is perhaps open to objection in that these animals differ so widely from mankind in their susceptibility to the infection. He finds that, though he cannot save the lives of infected guinea-pigs by treatment with his tuberculin, yet those so treated live longer than the controls. He finds also that if the lethal dose of tuberculin for an infected guinea-pig be determined, and if this dose be mixed before injection with serum from a normal guinea-pig, on the one hand, and with serum from a guinea-pig which has received injections of tuberculin, on the other, the animal which receives the latter mixture lives considerably longer than that to which the former mixture is administered. Injections of tuberculin do not produce immunity, and the so-called intensive treatment is accordingly irrational. The optimum dose must be determined by clinical observation, and this quantity continued for subsequent doses so long as its good effect continues, according to the method of Professor Sahli. Unfortunately treatment with tuberculin does not suit all cases, and it is impossible to know, except by experiment, which are suitable. In any case it is important to have recourse to the remedy early, and not to reserve it as a last resource when other measures fail.

---

[1] London: J and A. Churchill. Price 1s.

THE DOSAGE OF LOCAL ANÆSTHETICS.

IN the *Journal of the American Medical Association* of Jan. 17th Dr. A. H. Miller has emphasised the necessity for care in the dosage of the local anæsthetics, even those considered the safest. They all have a general effect depending on the dose. The toxicity of cocaine led to the substitution for it of other drugs which are less toxic, but cannot be considered entirely safe. It is unfortunate that their dosage is generally not given by manufacturers and is impossible to find in medical literature. What is given is strength of solution, and the dangerous inference may be drawn that any amount of a solution of that strength may be used with safety. The dosage is calculated for the local effect without considering the general effect. The result is shown by a series of 103 cases reported to the Providence Society of Anæsthetists in which alypin, one of the safest of the local anæsthetics, was used. Of these 35 were minor surgical operations and 68 genito-urinary operations. In 100 of the cases there was satisfactory anæsthesia, in 2 the anæsthetic caused serious difficulty, and in 1 death. In the last case the patient was a healthy man, aged 39 years, who was about to undergo the operation of dilatation of a stricture of the urethra. About 2 drachms of a 10 per cent. solution alypin were introduced into the urethra and bladder. Two minutes later he cried out and had a general convulsion. During the next ten minutes about half-a-dozen such convulsions followed. Respiration ceased in seven or eight minutes and at the end of ten minutes the pulse had stopped beating. Artificial respiration and stimulation were tried without avail. In another case a healthy man was about to have sounds passed for retention of urine. An unmeasured quantity of a 10 per cent. solution of alypin was introduced into the urethra and bladder. After about five minutes there was a general convulsion. The pulse became imperceptible and the respiration ceased. The patient was revived with difficulty after about two hours' work. In the third case about 1½ drachms of a 10 per cent. solution of alypin were introduced into the urethra and bladder for dilatation of a stricture. In three minutes the patient became unconscious, and after about five minutes had a severe general convulsion. The respiration ceased, the pupils were widely dilated, and the face was somewhat cyanotic, but the pulse remained good. The treatment consisted in artificial respiration and the inhalations of oxygen. In 10 minutes the danger seemed to be passed and recovery ensued.

ST. GEORGE'S HOSPITAL.

ON Thursday in last week a special court of governors of St. George's Hospital, presided over by Lord Greville, was held in accordance with the notices published in these columns. As a result of the deliberations the house committee received, on the motion of Sir Henry Burdett, power to refer to a committee of governors the consideration of the laws of the institution. The intention, if possible, of amalgamation with the Westminster Hospital is kept to the front by the agreement that when the occasion arises a joint committee of the two hospitals will be appointed. The unfortunate episodes which led to the resignation of the presidency of the hospital by H.R.H. the Princess Christian were met by a resolution regretting that an impression had been given that the proper authority of the president of the hospital had been resisted, and acknowledging the right of the Princess Christian to institute an independent inquiry. In moving a resolution, which was duly passed, appointing Lord Plymouth and Mr. West honorary life governors of the charity, Dr. John Cahill, in a wise little speech, explained that Mr. West had not sought for a salaried post in the hospital, and would not have entertained appointment thereto had he not been under the belief that the governors of the charity approved of what was being done. Dr. Cahill pointed out that the various differences of view amongst the governors had not impaired the high quality of the service given by St. George's Hospital to the sick poor.

DIABETES INSIPIDUS AND INFANTILISM.

THE effects of disturbance of the functions of the ductless glands, whether they be considered as acting together or separately, may be divided provisionally into two groups. There are, first, alterations of the nature of a dystrophy, as in acromegaly, infantilism, &c.; and, secondly, there are profound modifications of metabolism, as in diabetes mellitus and glycosuria, occurrence of which in disease of the ductless glands is common. Sometimes a condition of diabetes insipidus has been noted, and various investigators have remarked its association with experimental lesions of the pituitary body. Cushing has found that in a number of his surgically treated patients an unaccountable post-operative polyuria has occurred. A patient with moderate signs of hypopituitarism and normal urinary output, developed an extreme diabetes insipidus (10 or 11 litres in the 24 hours) for three months after a simple sellar decompression. Further, the same observer has often noted diabetes insipidus in animals after operation on the hypophysis. It has long been recognised that a transient hemianopia—hemianopia fugax—is sometimes associated with diabetes insipidus, but the real significance of the fact is only now being appreciated. According to Futcher, in a large number of recorded cases of diabetes insipidus both hemianopia and primary optic atrophy have been described. Schäfer and Magnus were the first to show that extracts of the posterior lobe of the pituitary gland possess diuretic properties of high degree, and Schäfer and Stiles have used such extracts clinically as diuretics. It is therefore clear that integrity of function of the hypophysis is intimately linked with control over urinary output, and that the appearance of polyuria or diabetes insipidus as a clinical symptom must at once direct attention to the matter of hypophyseal function. In the *Nouvelle Iconographie de la Salpêtrière*[1] MM. P. Lereboullet, M. Faure-Beaulieu, and E. Vaucher have published an interesting case exhibiting a combination of diabetes insipidus and infantilism. The patient was a young man, aged 24, who came under observation in January, 1913. He had developed normally up to the age of 14. Very shortly after a shock, sustained by involuntary immersion in cold water through falling out of a canoe, he began to pass large quantities of urine, 7 or 8 litres a day, and to suffer from polydipsia. These symptoms have persisted, but there has never been either sugar or albumin in the urine. At the age of 16 the patient's teeth all dropped out in the course of a few months as the result of painful ulceration of the gums. A year or two later generalised eczema of severe type appeared and has proved very intractable. On examination the youth was found to present extremely well-marked signs of infantilism. There was no hair on face or pubes, and only one or two sparse hairs in the axillæ. His voice had not "broken." There was double testicular atrophy, and the penis was very small, like an infant's. There was complete absence of sexual desire and power. No objective ocular signs were found, however, and the sella turcica was seen radioscopically to be of normal size and appearance. The patient's mental condition was quite good. While under observation he often passed as much as 10 litres of pale limpid urine in the 24 hours. Hypophyseal, thyroid, testicular, and pancreatic extracts were tried in turn during four months, but all failed to modify the patient's symptoms materially. The authors who have published the case are of the opinion that the condition is due to defect of function of the pars intermedia, usually described as belonging to, or at least mainly associated with, the pars posterior or nervosa of the pituitary gland. A number of clinical cases have now been reported where diabetes insipidus occurred with other definite indications of pituitary disease. Simmonds has published a case of tumour of the posterior lobe in which a polyuria of 19 litres in the 24 hours occurred. Franck has recorded a case of attempted suicide with a revolver in a man, aged 39, who, not long after shooting himself in the right temple, began to put on fat and developed a well-marked diabetes insipidus. Radiography showed clearly a ball occupying the posterior section of the sella turcica. Marie and Boutier have described a similar combination, as have Morley Fletcher, Berblisiger, Williams and Belfield, and others. Farini has treated a case of diabetes insipidus systematically with pituitary extract, but was able to control it and reduce it only as long as the treatment was active; whenever the latter ceased polydipsia and polyuria returned. There are, no doubt, difficulties in regard to the actual mechanism of production of the symptoms concerned. It is held at present that infantilism is associated with diminution of function of the anterior lobe, a hypopituitarism, while apparently the diabetes insipidus is a sign of liberation of an excess of posterior lobe secretion, a hyperpituitarism. On the one hand, however, different parts of the gland seem to be involved in the production of these two conditions, and, on the other, the study of the syndromes occurring in the course of disease of other ductless glands has accustomed us to analogous physiopathological dissociations.

A RARE FORM OF ABSCESS IN APPENDICITIS.

AT a meeting of the Académie de Médecine on Jan. 20th M. Routier reported a case of appendicitis in which an abscess formed in a very unusual situation—in the mesentery. A woman, aged 24 years, previously quite well, was awakened in the night of Jan. 30th, 1912, by severe abdominal pain. As she was menstruating she attributed the pain to this condition. But next day the temperature was 104·3° F. and she was very prostrate. A purgative was given, but it was vomited. On the third day her medical attendant, finding gurgling in the right iliac fossa, diagnosed typhoid fever. Then the spleen appeared to enlarge, which confirmed his diagnosis, and he sent the patient to hospital. Widal's test and blood culture were performed with negative results. For a fortnight attacks occurred every five days, characterised by rises of temperature to 104° or 105·8°, followed by shivering and chattering of the teeth. Finally, a painful point to the left of and a little below the umbilicus became manifest. On palpation there seemed to be a swelling at this spot. The patient continued in a prostrate condition and suffered from constant nausea. M. Routier then saw her in consultation. He found the whole abdomen supple except at the spot mentioned, where there was a painful indurated zone of the size of a 5-franc piece. He did not make a definite diagnosis, but considered that operation was necessary, and that probably an abscess would be found. This was done on Feb. 20th. The peritoneum and intestinal coils were found normal. On separating the latter an induration was found at the root of the mesentery, the anterior layer of which was raised by the swelling. The pulsations of the aorta were transmitted to it. Having carefully isolated the field of operation, two fingers of the left hand were passed in front of the aorta beneath the swelling and a vertical incision was made. A large spoonful of thick creamy pus escaped. The cavity of the abscess was explored without result. A wick-drain was inserted, and the abdominal cavity was closed. The patient at first considerably improved; the pain disappeared, but the temperature remained 104°, and she died on March 4th. The origin of the abscess was a mystery until the necropsy, which showed that an appendix in an abnormal situation—between the two layers of the mesentery—had perforated. From the perforation a brightness, which is due to the white light reflected from the pastille, is dulled if necessary by the interposition of a standard neutral tint composed of a fraction or multiple of one unit of each of the red, blue, and yellow glasses combined, which absorbs the white light. For example, the colour sensation transmitted from the unexposed pastille in daylight is: yellow, 11·5; green, 1·5; light, 1·5; for 1·5 of neutral tint was required to absorb all the white light transmitted. Similarly for 1/4 and 1/3 B under bright daylight 0·5 and 0·2 neutral tint were required respectively.

---

[1] September-October, 1913, p. 410.

The following precautions should be taken when using the radiometer:—

In daylight: 1. This should be diffused and as white as possible. On no account should measurements be made near sunlight. 2. Keep the instrument vertical, avoiding shadows.

Using electric light: 1. Use an 8 c.p. carbon filament lamp with frosted glass so arranged with a shade that the eyes are protected from the light. The shade should be black, not coloured. Those used for microscopes do very well. The lamp should be in good condition. 2. Keep the instrument vertical, the pastille being about 8 inches away from the lamp.

In both cases: 1. Examine as quickly as possible, for the pastille fades even in electric light. 2. The standard white background must always be used and kept clean.

The Standards.

1. 1/4 B. This will be useful to those people who work with the pastille on the skin in tinea. If used in this way without any other control a new pastille should always be exposed. In daylight 0·4 neutral tint is required on the pastille side to absorb the white light. Both this standard and the 1/2 B can be used in treatment of deep-lying tissues with filtered rays when it is required to bring the tube as close as possible to the skin. 2. 1/3 B is the dose employed in the treatment of various skin affections. 0·2 of neutral tint is sometimes needed. 3. 1/2 B is a useful standard: (*a*) It is employed in the treatment of certain diseases of the skin; (*b*) it can be used in tinea by those who use the "1/2 time distance" method. If the usual anticathode skin distance is 15 cm., and this is reduced by 1/4 to 11·25 cm., 1/2 B at the original half-way position 7·5 cm. from the anticathode will mean that the scalp will receive 1/4 B. I have not at present had any experience of this method as recommended by Hampson and further modified by Batten,[2] but in view of the readiness with which this tint can be appreciated in the radiometer the procedure should be rendered easier. Further at a point on the curve just below 1/2 B—namely, 4/10 B—the colour is a yellow with a trace of blue. Using this standard, which can be supplied if required, one would be able to give the equivalent of 4/5 B in the true half-way position, although, of course, the margin for error is smaller.

The Epilation Doses.

4. 4/5 B usually produces epilation without erythema, but cannot always be relied upon for this purpose. It is frequently insufficient for the top patch in tinea and for very stiff beards; for these the full dose should be given. 5. 1/1 B always produces epilation. There is usually some transitory erythema at about 18 days, better marked on the skin near the ears and at the back of the neck if unprotected. 6. 1·2 B is the highest dose I have ever employed in tinea. Epilation of course results, and is always accompanied by erythema and sometimes by transient dermatitis on the unprotected skin. If any septic foci are present on the scalp there is a smart inflammatory reaction around them. This form of dermatitis starts as an erythema and is followed by a slight desquamation, but the whole process clears up in a week under soothing applications. In the few cases where this dose was reached the re-growth of the hair, though slower than after the smaller doses, was quite satisfactory. I should imagine that this point was very nearly the limit consistent with safety in tinea. I have given it with success as an unscreened dose for rodent ulcer, allowing a full month to elapse between the first and second dose.

Standards for higher doses up to 4 B can be easily made, but as these doses would of course only be given with a filter, there is not much object in using such standards, as it is becoming the general practice to measure the dose with the pastille under the filter.

Where very accurate doses are required new pastilles should be used. The exposed pastille never returns exactly to its original tint; there is less green even after thorough bleaching. This fact makes very little difference to the orange part of the curve—that is to say, tint B is not reached appreciably quicker provided that the pastille has not been used more than three times at most.

This instrument has been in daily use in the X ray Therapeutic Department of St. Thomas's Hospital for some months, and the results in tinea work have been most satisfactory. During 1913, the first year of the department, about 200 cases of tinea were treated. At first we were always in doubt with regard to any dose below the full B, and several cases had to be done a second time. Since these standards have been employed there has only been one case which has needed a second sitting. In this there was incomplete epilation after a full dose over an area occupied by a large known nævoid patch on the scalp. We use 4/5 or 9/10 B for all except the top patch, which receives the full dose. There have been no cases of permanent baldness and none of dermatitis except the transitory form with 1·2 B already mentioned.

The advantages of this radiometer over others where Sabouraud's pastille is employed are:—

1. The colour standards are constant and invariable in tint, easily kept clear, and do not fade. The smaller differences between the fractional doses are readily appreciated.

2. They have all been verified experimentally in tinea work, and any fractional or multiple dose can be standardised.

3. There is provision of a separate series for daylight and standard artificial light. A series could be worked out for any constant source of light if required.

The pastille should be examined in its holder if possible. The instrument can be adapted to any form of pastille holder. The makers are Tintometer Limited, The Colour Laboratory, Salisbury.

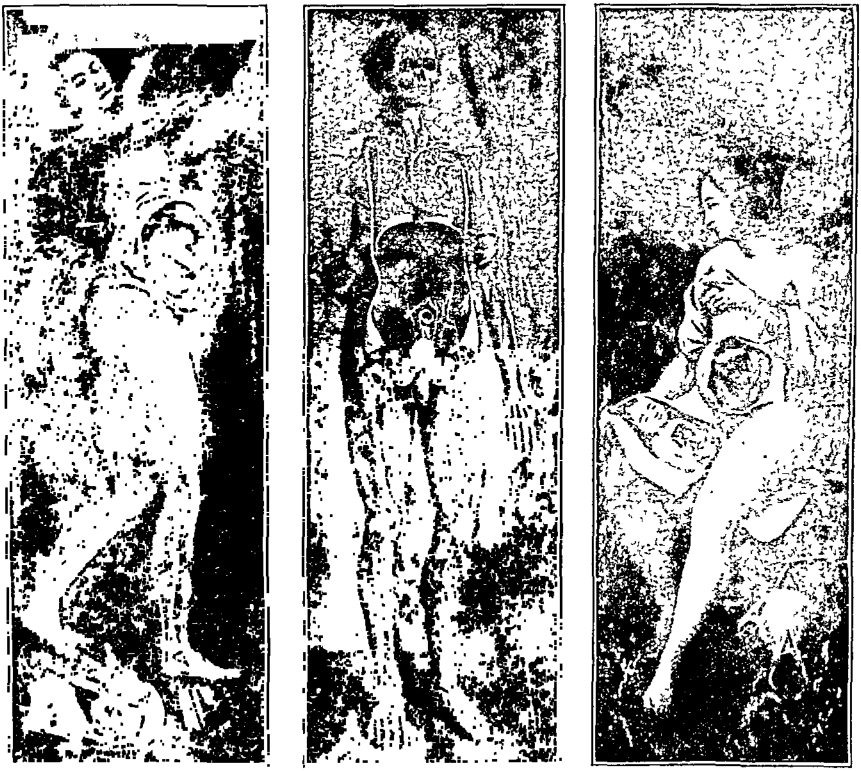
SOME PANELS BY JACQUES GAUTIER D'AGOTY.

There are at the present moment on private exhibition in Paris 12 painted panels attributed to Jacques Gautier d'Agoty which would form a remarkable adornment to any great medical library or institute if they should have the good fortune to find a generous purchaser. We reproduce here three of the pictures, the enormous reduction being intimated by the fact that each panel measures 2·30 metres in height by 0·70 metre in breadth.

The origin of the panels, though their authenticity can hardly be challenged, is a little obscure. Jacques Gautier d'Agoty, a member of the Dijon Academy of Sciences, was born in Marseilles in 1710, and died in Paris at the age of 75. He was a philosopher, a distinguished anatomist, an engraver, and, *teste* these panels, a painter of remarkable quality. He published in 1745 an illustrated work under the title "Myologie Complète en Couleur et Grandeur Naturelle," which was illustrated by 20 plates with letter*press furnished by Jacque François Duverney, lecturer and* physician of the Jardin du Roy, and brother of the great Guichard Joseph Duverney. This book, separately or bound up with another work on the brain and the special organs of sense, illustrated from dissections made by Duverney, and sometimes including a third work on the general anatomy of the viscera with 18 coloured plates, is occasionally catalogued by booksellers, so that the 46 plates are familiar to some bibliophiles. In 1752 d'Agoty wrote a work entitled "Natural History," which dealt with philosophy, art (especially painting), science, and physical development, which was illustrated by 10 plates. He published also a refutation of the Newtonian theory of fundamental colours, under the title of "Chroa Genesie," in 1750, and conducted a controversy on the same subject in the London scientific papers of that year.



Reproductions from photographs of three of the D'Agoty panels.

The 12 panels which are now in Paris, in the possession of M. Oscar Scarpa, at 12, rue Pierre Joignaux, Bois Colombes, appear to be certainly the origins of some of the plates, and not to have been themselves painted from the plates. This is in direct contradiction to the suggestion that they might have been painted by d'Agoty's son Arnaud, who wrote several medical works illustrated by coloured plates.

The technique of the 12 panels is admirable, and the delicacy and beauty of the women's faces show them to be the work of a finished painter. The existence of the panels has long been an open secret, indeed, a description of them can be found in the "Bibliothèque National," *and their history, taken in connexion with the numerous* plates illustrating d'Agoty's works, presents many interesting problems to the art critic. Their proper home is certainly some great institution, like the École de Médecine at Paris or the Museum of the Royal College of Surgeons of England.

after the minimum of 19°, the maximum was as low as 31°. Rain fell only on 10 days, and the total, 0·54 in., was no more than 50 per cent. of the January average. As many as 17 days—most of them during the cold spell—were entirely sunless, and the total sunshine for the month was only 26 hours, against an average of 44 hours. Both Bath and Nottingham had the same minimum temperature as Kew, but their mean maximum was 1° or 2° higher. Bath had no more than 7 days with rain, giving a total equal to that at Kew, but at Nottingham rain fell on 18 days, and yielded an aggregate of 1·1 in. Bath was more sunny than Kew, having a total of 38 hours—only 8 hours less than the normal—while at Nottingham there were no more than 21 hours, just half the average. For many days the coast of Kent was the coldest part of the kingdom. Further west the cold became gradually less keen. At Brighton the mean maximum temperature was a degree lower than at Kew, while the mean minimum was only a degree higher. At Bournemouth the mean maximum was 43°, or a degree higher than at Kew, and the mean minimum 35°, 2° higher than at Kew. At Torquay the corresponding figures were 45° and 37·5°, at Newquay 43° and 39°, and at the Scilly Isles 48° and 41°. Sunshine was more at Brighton than at the resorts further west. Its total number of hours, 60, was 6 more than the average, and 11 hours more than at Bournemouth, while it exceeded the totals at Newquay and Scilly by 23 hours. Torquay, generally among the brightest spots, and with a January average of 66 hours, experienced a very dull month, its total sunshine being only 28½ hours. As in London and central England the rainfall along the south and south-west coasts was much less than the normal, as well as in the Channel Islands. During the daytime Jersey had the same temperature as Torquay, but its mean minimum temperature of the night was 1½° lower. The Peak region of Derbyshire was seldom exceptionally cold. At Buxton the mean day temperature was 39°, and that of the night 32°, while the lowest temperature of the month was 5° higher than the 19° recorded in London.

Abroad.

The south and south-west of England compared very well with the Riviera and the south-west corner of France in the matter of temperature. At Nice the sheltered thermometer fell to 32° or below on 7 nights, and the mean minimum was only 35°, the same figure as Bournemouth, and some degrees below that on the coasts of Devon and Cornwall and at Scilly. The mean maximum was, however, higher than at any place in this country, although it was only 1° above that at Scilly. Biarritz was as cold at night as Brighton, and colder than all the English resorts to the westward, while its mean afternoon maximum, 45°, only equalled that at Torquay and Jersey, and was 3° below the figure at the Scilly Isles. Compared with the interior of France, the Netherlands, and Germany, the cold in this country was nothing. At Paris the mean maximum temperature was 37°, 2° lower than at Buxton, while the mean minimum was 25°, and the lowest reading recorded (on the 24th) 12°. The weather was, however, generally bright, and the total amount of sunshine as high as 68 hours, or 40 hours more than fell to the lot of London. At Brussels rain and snow were rather frequent, and the temperature a degree colder than at Paris both during the day and night. The lowest minimum temperature was 11°, and, as at Paris, the thermometer remained continuously below the freezing point for many consecutive days. At Berlin the temperature was lower than at Brussels, its mean maximum being 33° and its mean minimum 22°. On several nights the thermometer descended to 12°, and on some of the days rose no higher than 20°. Frost was frequent in northern Italy and occasionally occurred in the southern districts. Considered generally, however, the climate south of Rome was milder than the Riviera and nearly as bright. Maximum temperatures above 50° were very common, and very occasionally the thermometer ascended to within a few degrees of 60°. The Madeira Islands were too far south to be influenced by the cold current of wind that brought winter to Europe, and the mean temperature of the month was about equal to that of early June in England. The mean maximum was as high as 66° and the mean minimum no lower than 56°. On several days the thermometer reached 70°, while not a single night was colder than 52°. Rain fell on 7 days, and gave a total of 1·5 in.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the fourteenth meeting of the Royal Commission on Venereal Diseases evidence was given by Sir Arthur Downes, the senior medical inspector for Poor-law purposes of the Local Government Board, and by Dr. E. B. Sherlock, of the Metropolitan Asylums Board.

Sir Arthur Downes stated that the general opinion expressed by Poor-law medical officers in London was that venereal diseases are less prevalent and milder in type amongst the poor than they were formerly. The opinions of provincial medical officers varied somewhat, but on the whole they appeared to be to the same effect; there were, however, some exceptions, chiefly in seaport towns. He gave it as his general impression that the prevalence of venereal disease amongst the very poor was not large. He explained that under the Poor-law venereal diseases were on exactly the same plane as all other diseases, and that it was the duty of Poor-law authorities to afford relief to all persons in urgent need of any important assistance, such as medical assistance, which they were unable to provide for themselves.

Sir Arthur Downes said that although Poor-law authorities did not necessarily insist on venereal cases being treated in an institution, he believed that a considerable proportion of the authorities objected to affording outside treatment in the case of these diseases. This, he thought, might have the effect of deterring some people from coming for treatment. At the present time the use of the more recent methods of diagnosis and treatment in connexion with venereal diseases was confined to a number of the more important Poor-law authorities. In some of the large unions salvarsan treatment was in use and the Wassermann test was applied. In London a very fine system of Poor-law infirmaries had been provided, almost all of which were equal in their administration to general hospitals; most of these infirmaries were able to set apart special wards for venereal cases, though they could not always reserve those wards entirely, the number of cases not being sufficient to justify their setting aside beds which were very valuable. Most of the London unions sent their Wassermann tests to the Wassermann Institute or the Clinical Research or some pathological laboratory. In the case of the small country unions laboratory provision could not be expected, but the powers of the guardians to pay for diagnosis and to send patients for treatment in special institutions were very elastic; they had also wide powers of combining amongst themselves for any special purpose.

Referring to the recommendation of the Royal Commission on the Poor-laws that subject to certain safeguards against abuse the public assistance authority should have power to detain cases of venereal disease when medically certified to be dangerous to others, Sir Arthur Downes said that he could only support this proposal if the detention was not of a penal character and was so arranged as to be as little deterrent as possible.

At the fifteenth meeting evidence was given by Dr. Helen Wilson.

Dr. Wilson said that it was now generally recognised that it was quite futile to attempt for venereal diseases such isolation as was practised in regard to acute infectious diseases, the main reason being that in a large proportion of cases venereal diseases did not prevent the sufferer from following his ordinary avocation, that they were easily concealed, and that there were strong motives for concealment. The objects to be aimed at were, first, to bring every sufferer under efficient treatment at the earliest possible moment, thereby shortening the infective period; and secondly, to secure his own intelligent coöperation both for his own cure and for the protection of his associates. She did not think that compulsory notification would ever be a material help in diminishing these diseases, but that any attempt to deal with these diseases otherwise than on voluntary lines would array a tremendous amount of opposition. If voluntary methods were given a fair and intelligent trial she was convinced that the residuum of cases would be comparatively small and that probably means could be found for dealing with them.

As regards the organisation of medical treatment, Dr.

Wilson thought that the hard and fast line which has been drawn between these diseases and all others should be abolished. *Admission to institutions and treatment of the* diseases should not be governed by inquiries as to the method in which the disease was contracted, and the nursing and all other arrangements should be as good in the wards for the treatment of these diseases as in any others. Names like "Lock" and "Magdalene" for special wards or hospitals had a deterrent effect and should be avoided. She laid stress on the importance of providing evening clinics for out-patients.

Dr. Wilson was of opinion that further instruction was needed for medical students and nurses, and that the education of the general public in matters of sex hygiene was of the highest importance. She doubted whether it would be wise to introduce systematic class instruction in elementary schools, and she was certainly of opinion that in these schools there should be no instruction dealing with diseases. In the first instance, parents and teachers needed preparation for the work of instructing children. She understood that in some few training colleges this matter was already receiving attention, and teachers were being trained, not with the object of giving class lessons, but to enable them to speak to the older children privately when they saw occasion to do so. In some schools in America the plan had been tried of inducing the mothers to come and hear about the subject in the first place and afterwards of beginning a course of lessons to the girls, the mothers being invited to be present the whole time. Dr. Wilson considered this arrangement of teaching the girls in the presence of the mothers to be an admirable one as helping to secure what was most wanted—that the girls should be in the position to speak frankly to their mothers in private about the subject.

At the sixteenth meeting Surgeon Scott, R.N., who was until recently in charge of the Naval Hospital at Chatham, gave evidence respecting the methods of treatment and results obtained in naval hospitals.

AN INQUEST AT WORCESTER.

THE coroner for Worcester, Mr. W. B. Hulme, on Feb. 10th held an inquiry into the death of Mrs. Daniels. Before

the case was that Mr. Burden, who, so far as he knew, had no qualification, had taken it upon himself to treat her. It would be a most serious matter if Mr. Burden had treated her improperly.

Evidence was given by the daughter of the deceased, who said her mother had been unwell for a little over a year, and had been treated by Mr. Burden. When she had to go to bed three months ago Mr. Burden saw her, and said she had had an

the exception of the thickening of the edge of one of the valves. The stomach was empty, and the large bowel, which had an extremely thin wall, had fluid contents. Examining the kidneys, he found that the cortex was reduced in width, and the capsule of the kidney was unduly adherent to the substance of the kidney. The right kidney weighed 5½ ounces, which was slightly enlarged. There was no solid matter in the whole of the intestines, which was somewhat unusual unless there had been severe diarrhœa. He found no sign of tapeworms *in the intestines. Taking into consideration the fact that*

clivers, burdock root, figwort, blue flag root, black samson, black root, and motherwort—and asked the witness if he recognised any. Mr. Bates replied that he knew the names of some but not their action. In reply to a further question he said it was possible that she had been suffering from mucous colitis, which might have caused mucous casts, and

off. She had acute dermatitis supervening on a chronic eczematous condition. Her temperature was below normal, 98°F., and her pulse was about 80. She was only semi-conscious, and consequently could give no account of her symptoms. It was impossible for him to form a diagnosis of her actual disease. She was practically dying. He was present at the post-mortem examination, and he agreed with Mr. Bates as to what he found. He believed

to show the recognised posi-
inations they had to pass, but
the Coroner said he was afraid he could not allow questions on that. When Mr. Anthony went on to refer to the National Insurance Commissioners having made regulations

recognising herbalists, the Coroner remarked again that they could not go into those matters.

Mr. Anthony then maintained that Mr. Burden was entitled to give a notification which registrars must accept.

The Coroner: They can accept it as a notification, not as a certificate.

Mr. Anthony: But Mr. Burden says he gave it as a notification.

The Coroner: It speaks for itself, "I hereby certify."

The Coroner, addressing the jury, pointed out that Mr. Burden was not a duly registered medical practitioner, and he had taken upon himself to attend the deceased, and, except at the last moment, he refrained from advising the relatives to call in a doctor. He had said that he did not anticipate the woman's death. It was not necessary for a man to be a duly registered medical practitioner to enable him to treat patients if he had the requisite knowledge and made common and reasonable use of that knowledge. Mr. Burden's knowledge was nothing like what an ordinary medical man's would be. He would have very little opportunity of finding out what the deceased was suffering from. A medical man would have been able to diagnose her disease. The doctors had told them that the woman had diseased kidneys, and that they could not say if she had been attended by a doctor that she would still be living. They also said that none of the herbs mentioned would have been injurious. If that was so any case against Mr. Burden fell to the ground. Unless the doctors could say that the deceased's life was shortened by what Mr. Burden did there could be no charge against him in any way.

Without any comment, beyond expressing sympathy with the relatives, the jury returned a verdict in accordance with the medical evidence.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8407 births and 5430 deaths were registered during the week ended Saturday, Feb. 14th. The annual rate of mortality in these towns, which had been 17·5, 18·4, and 16·5 per 1000 in the three preceding weeks, further declined to 15·6 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 17·4, against a corresponding rate of 17·5 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·7 in Ilford, 7·7 in Walthamstow, 8·4 in Eastbourne, 8·5 in Enfield. and 9·4 in Hornsey, to 22·2 in Barnsley, 22·7 in Rochdale and in Gateshead, 23·9 in Merthyr Tydfil, 25·5 in Bury, and 27·0 in Burnley.

The 5430 deaths from all causes were 320 fewer than the number in the previous week, and included 401 which were referred to the principal epidemic diseases, against 400 and 375 in the two preceding weeks. Of these 401 deaths, 129 resulted from whooping-cough, 89 from measles, 68 from infantile diarrhœal diseases, 64 from diphtheria, 37 from scarlet fever, and 14 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·2, against 1·2 and 1·1 per 1000 in the two preceding weeks. The deaths attributed to whooping-cough, which had steadily risen from 64 to 116 in the five preceding weeks, further increased to 129 last week, and caused the highest annual death-rates of 1·1 in Leicester and in Birkenhead, 1·2 in Newport (Mon.), 1·6 in Halifax, 1·7 in Swansea, *and* 2·2 *in Rochdale*. The deaths referred to measles, which had been 70. 79, and 64 in the three preceding weeks, rose to 89 last week; the highest death-rates from this disease were 1·6 in Middlesbrough, 1·9 in Barnsley and in Cardiff, 2·6 in Swansea, 5·0 in Dudley, and 5·7 in Burnley. The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 68, 93, and 66 in the three preceding weeks, were 68 last week; of this number 17 were recorded in London, 5 in Birmingham, 4 in Manchester, and 3 each in Leicester, Liverpool, and Bradford. The deaths attributed to diphtheria, which had been 68, 85, and 70 in the three preceding weeks, further declined to 64 last week, and included 11 which were registered in London, 7 in Birmingham, 4 in Manchester, and 3 each in East Ham, Portsmouth, Cambridge, and Walsall. The deaths referred to scarlet fever, which had been 41, 29, and 38 in the three preceding weeks, were 37 last week, of which 10 occurred in Birmingham, 4 in London, 4 in Liverpool, and 3 in Salford. The fatal cases of enteric fever, which had been 17, 21, and 21 in the three preceding weeks, fell to 14 last week, and included 7 in London and 2 in Sheffield.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3567, 3599, and 3554 at the end of the three preceding weeks, had further declined to 3537 on Saturday last; 428 new cases were admitted during the week, against 375, 460, and 379 in the three preceding weeks. These hospitals also contained on Saturday last 1149 cases of diphtheria, 283 of whooping-cough, 82 of enteric fever, and 74 of measles, but not one of small-pox. The 1250 deaths from all causes in London were 190 fewer than the number in the previous week, and corresponded to an annual death-rate of 14·4 per 1000. The deaths referred to diseases of the respiratory system, which had been 421, 425, and 347 in the three preceding weeks, further declined to 262 last week, and were 101 below the number recorded in the corresponding week of last year.

Of the 5430 deaths from all causes, 156 were attributed to various forms of violence, and 388 were the subject of coroners' inquests. The causes of 31, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Nottingham, Portsmouth, and in 70 other smaller towns. Of the 31 uncertified causes of death 5 were recorded in Birmingham, 4 in Liverpool, 3 in Rochdale, 2 in Stoke-on-Trent, and 2 in Coventry.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1159 births and 743 deaths were registered during the week ended Saturday, Feb. 14th. The annual rate of mortality in these towns, which had been 20·9, 20·0, and 18·4 per 1000 in the three preceding weeks, further declined to 16·9 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 19·5, against a corresponding rate of 17·4 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 9·2 in Perth, 10·8 in Hamilton, and 14·1 in Clydebank, to 20·5 in Ayr, 21·6 in Kirkcaldy, and 21·8 in Coatbridge.

The 743 deaths from all causes were 64 fewer than the number in the previous week, and included 75 which were referred to the principal epidemic diseases, against numbers declining from 100 to 68 in the three preceding weeks. Of these 75 deaths, 41 resulted from measles, 12 from diphtheria, 8 from infantile diarrhœal diseases, 7 from scarlet fever, 4 from whooping-cough, and 3 from enteric fever, but not one from small-pox. These 75 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·7, against 1·2 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 51, 48, and 34 in the three preceding weeks, rose to 41 last week, of which number 20 were recorded in Glasgow, 8 in Edinburgh, 3 in Paisley, and 2 each in Leith, Greenock, and Ayr. The deaths referred to diphtheria, which had been 19, 14, and 15 in the three preceding weeks. fell to 12 last week, and included 3 in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 9, 12, and 7 in the three preceding weeks, were 8 last week, 5 of which occurred in Glasgow. The deaths attributed to scarlet fever, which had been 15, 10, and 6 in the three preceding weeks, were 7 last week, and included 2 in Glasgow and 2 in Edinburgh. The 4 deaths referred to whooping-cough, all of which were recorded in Glasgow, were 2 below the average in the earlier weeks of the quarter. Of the 3 fatal cases of enteric fever 2 occurred in Glasgow and 1 in Greenock.

The deaths referred to diseases of the respiratory system, which had declined from 230 to 179 in the four preceding weeks, further fell to 147 in the week under notice; 30 deaths were attributed to various forms of violence, against 36 and 33 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 638 births and 437 deaths were registered during the week ended Saturday, Feb. 14th. The annual rate of mortality in these towns, which had been 23·8, 24·0, and 21·9 per 1000 in the three preceding weeks, further declined to 18·9 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these Irish towns averaged 22·6 per 1000; in the 97 large English towns the corresponding rate did not exceed 17·4, while in the 16 Scotch towns it was equal to 19·5 per 1000. The annual death-rate last week was equal to 20·4 in Dublin (against 14·4 in London and 16·8 in Glasgow), 18·6 in Belfast, 19·0 in Cork, 5·1 in Londonderry, 23·0 in Limerick, and 28·5 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 17·1 per 1000.

The 437 deaths from all causes were 70 fewer than the number in the previous week, and included 35 which were referred to the principal epidemic diseases, against 21 and 37 in the two preceding weeks. Of these 35 deaths, 9 resulted from scarlet fever, 9 from whooping-cough, 8 from infantile

* Including membranous croup.

† The death rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

diarrhœal diseases, 5 from measles, 2 from diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5 per 1000; in the 97 large English towns the corresponding rate did not exceed 1·2, while in the 16 Scotch towns it reached 1·7 per 1000. The deaths attributed to scarlet fever, which had been 2, 5, and 10 in the three preceding weeks, were 9 last week, of which 6 occurred in Belfast and 2 in Dublin. The deaths referred to whooping-cough, which had been 10, 7, and 6 in the three preceding weeks, rose to 9 last week, and included 6 in Belfast and 2 in Dublin. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 9, 6, and 7 in the three preceding weeks, were 8 last week, of which 5 were recorded in Dublin. The deaths attributed to measles, which had been 8, 3, and 8 in the three preceding weeks, fell to 5 last week, and were all registered in Dublin. The 2 deaths referred to diphtheria, which occurred in Dublin and Drogheda respectively, were slightly below the average in the earlier weeks of the quarter. The fatal cases of enteric fever were recorded in Dublin and Limerick respectively.

The deaths referred to diseases of the respiratory system, which had been 153, 157, and 132 in the three preceding weeks, further fell to 99 in the week under notice. Of the 437 deaths from all causes, 115, or 26 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 28, or 6·4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes last week did not exceed 0·6 per cent.

VITAL STATISTICS OF LONDON DURING JANUARY, 1914.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 8·3 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 10·4, 11·0, and 9·0 per 1000 respectively. The lowest rates last month were recorded in the City of Westminster, St. Marylebone, Hampstead, Stepney, and Wandsworth; and the highest rates in Islington, Southwark, Battersea, Deptford, and Lewisham. The prevalence of scarlet fever showed a considerable decline from the numbers recorded in other recent months; this disease was proportionally most prevalent last month in Fulham, Islington, the City of London, Southwark, Lambeth, Battersea, Camberwell, and Deptford. The Metropolitan Asylums Hospitals contained 3543 scarlet fever patients at the end of last month, against 3517, 4006, and 3810 at the end of the three preceding months; the weekly admissions averaged 400, against 512, 581, and 445 in the three preceding months. Diphtheria was slightly less prevalent than it had been in any of the three preceding months; the greatest proportional prevalence of this disease was recorded last month in Paddington, Stoke Newington, Hackney, Bermondsey, Greenwich, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1190, 1188, and 1099 at the end of the three preceding months, had further declined to 1092 at the end of last month; the weekly admissions averaged 153, against 184, 158, and 146 in the three preceding months. The prevalence of enteric fever was rather greater than it had been in December. Among the several metropolitan boroughs this disease was proportionally most prevalent in Fulham, Hampstead, Islington, Holborn, Finsbury, and Lewisham. There were 65 enteric fever patients under treatment in the Metropolitan Asylums Hopitals at the end of January, against 77, 72, and 51 at the end of the three preceding months; the weekly admissions averaged 14, against 12, 11, and 9 in the three preceding months. Erysipelas was proportionally most prevalent in St. Pancras, Hackney, Finsbury, Shoreditch, Bethnal Green, Deptford, and Greenwich. The 22 cases of puerperal fever notified during the month included 2 each in Hampstead, Islington, Stepney, Poplar, Southwark, and Camberwell. Of the 4 cases of cerebro-spinal meningitis, 2 belonged to Poplar, and the 3 cases of poliomyelitis belonged respectively to Hammersmith, Bethnal Green, and Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the population of the several boroughs. During the four weeks ending Jan. 31st the deaths of 6379 London residents were registered, equal to an annual rate of 18·4 per 1000; in the three preceding months the rates had been 13·7, 13·5, and 14·9 per 1000 respectively. The death-rates last month ranged from 12·3 in Lewisham, 14·1 in Wandsworth, 14·9 in Hampstead, 15·5 in Stoke Newington, and 15·7 in Greenwich, to 20·1 in Bethnal Green, 20·2 in Paddington, 21·4 in Southwark, 22·4 in Stepney, 22·7 in Shoreditch, 22·8 in Bermondsey, and 23·4 in Finsbury. The 6379 deaths from all causes included 250 which were referred to the principal infectious diseases; of these, 27 resulted from measles, 17 from scarlet fever, 51 from diphtheria, 53 from whooping-cough, 16 from enteric fever, and 86 from diarrhœa and enteritis among children under two years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Hammersmith, Stoke Newington, Holborn, Battersea, and Lewisham; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Deptford. The 27 fatal cases of measles were 172 below the corrected average number in the corresponding period of the five preceding years; of these 27 cases 9 belonged to Deptford, 4 to Bermondsey, 3 to Camberwell, 2 to Stepney, 2 to Lambeth, and 2 to Greenwich. The 17 deaths from scarlet fever were 2 below the corrected average number, and included 3 in Camberwell and 2 each in Shoreditch, Bermondsey, and Wandsworth. The 51 fatal cases of diphtheria were 2 in excess of the corrected average number; the [illegible] mortality from this disease was recorded [illegible] y, Southwark, Bermondsey, [illegible] 53 deaths from whooping-cough were 38 fewer than the corrected average number; this disease was proportionally most fatal in Hampstead, Bethnal Green, and Southwark. The 16 deaths from enteric fever were equal to the corrected average number, and included 2 in Fulham, 2 in Islington, 2 in Hackney, 2 in Lambeth, and 2 in Wandsworth. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 57·1 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Staff-Surgeon Arthur Sylvester Bradley has been allowed to withdraw from His Majesty's Naval Service with a gratuity (dated Feb. 11th, 1914).

In accordance with the provisions of His Majesty's Order in Council of August 8th, 1911, Surgeon Lionel Caldbeck Esmonde Murphy has been placed on the Retired List (dated Feb. 12th, 1914).

The under-mentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet: Leonard Warren, Louis Leisler Greig, Ewen Cameron, Percy Frank Minett, Frederick George Goble, and Herbert Acland Browning (dated Feb. 10th, 1914).

The following appointments have been notified:—Fleet-Surgeons: W. E. Marshall to the *Duke of Edinburgh*, on re-commissioning; C. M. Beadnell to the *Shannon*, on re-commissioning; and H. Huskinson to the *Thunderer*. Staff-Surgeons: H. B. Hill to the *Highflyer*, and for Physical Training duties; P. T. Nicholls [illegible]; A. A. Forrester to the *Implacable*, [illegible] Edwards to the *Duke of Edinburgh*, on recommissioning; and E. F. Ellis to the *Alecto*, temporarily. Surgeons: C. V. Griffiths to the *Shannon*, on recommissioning; and R. M. Riggall to the *Pembroke*, additional, for disposal.

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentlemen have been appointed Surgeons:—William Norman Pickles, Edward Philip Punch, and Robert Traill Brotchie (dated Feb. 12th, 1914).

ROYAL ARMY MEDICAL CORPS.

Major Henry N. Dunn to be Lieutenant-Colonel, vice M. O'D. Braddell, retired (dated Feb. 4th, 1914;

Captain Benjamin A. Odlum is seconded for service under the Colonial Office (dated Jan. 1st, 1914).

Colonel G. D. Hunter has taken up duty as Assistant Director of Medical Services to the Allahabad Brigade. Colonel M. W. Russell has been selected for appointment as Assistant Director of Medical Services to the Malta Command, in succession to Colonel R. Porter, placed on half pay.

Lieutenant-Colonel D. D. Shanahan has arrived home for duty from Ootacamund. *Lieutenant-Colonel* J. Girvin has *been appointed to hold charge of the* Military Hospital at the Curragh Camp. Lieutenant-Colonel J. M. F. Shine *has* been appointed to hold charge of the Military Hospital at [illegible] Thorpe has embarked for a tour of service in India. Major [illegible] the Military Hospital [illegible] Major E. S Clarke [illegible] Major E. P. Connolly [illegible] Director of Medical [illegible] Second (Rawal Pindi) [illegible] Army in India. Major H. D. Packer has been placed under orders to embark for a tour of service in India. Major E. W. Slayter has been appointed to the Irish Command Major G St C. Thom has been appointed to Glasgow. TAUNTON AND SOMERSET HOSPITAL.—At the recent annual meeting of the subscribers to the Taunton and Somerset Hospital the financial statement showed a favourable balance The committee has decided to carry out considerable structural alterations in the hospital in order to provide a new operating theatre and anæsthetic room, and also to improve the children's wards and provide shelter for the use of patients. The scheme has been [illegible], the Hon. Mrs. Portman [illegible] H. B. Portman £1000, and [illegible]

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 414.)

XXXVII.—LONDON: ORGANISATIONS FORMED TO COMBAT THE ACT.

WE have seen that from the Provisional Medical Committee, framed at the instigation of the British Medical Association, other organisations, notably the National Medical Guild, emerged. To the London Medical Committee, as well as to the National Medical Guild, I have already referred—it may seem very belated at this time to explain the constitution of these bodies, but without doing so what is happening cannot be understood. I have had the great advantage of the help of Dr. C. Buttar in writing the following description of a complicated situation.

When the Representative meeting of the British Medical Association on Jan. 18th, 1913, declared the pledge to be no longer binding on members of the medical profession, various bodies which had contended hitherto for one common object under a variety of titles adopted pronounced views in somewhat different directions. At the same time certain new bodies sprang up or were evolved from older associations. The nomenclature of these bodies has become rather confusing, so that it is well to attempt to reduce matters to some sort of order and to endeavour to explain the objects at which each aims. They are not all bodies having their origin in London or confining their working to London, though it is convenient to describe them while the working of the Act in London is under consideration. The following definitions would seem to be fairly correct:—

1. *State Sickness Insurance Committee.*—A committee of the British Medical Association originally appointed to deal with negotiations on matters connected with the Insurance Bill. The title has now been changed to—
2. *Insurance Act Committee.*
3. *Provisional Medical Committees.*—Formed at the instigation of the State Sickness Insurance Committee in each insurance area. They consisted of members of the British Medical Association and of non-members, elected at meetings open to the whole profession in each area. The meetings were organised through the divisions of the Association. It was intended that, in the event of the Act and Regulations being rendered acceptable to the profession, these committees should become—
4. *Statutory Medical Committees* under the Act.
5. *British Medical Reform Committee*, formed in London, but now extinct.
6. *National Medical Union*, formed in Manchester, and now the federating body for non-panel associations.

These two organisations originally voiced the dissatisfaction at the methods adopted by the British Medical Association in its negotiations with the Government during the passage of the Bill.

7. *Edinburgh Medical Guild.*—A local body of similar views to the National Medical Union, now one of the associations federated to that organisation.
8. *London Medical Committee.*—Taking its origin from the Provisional Medical Committee for the County of London. A fighting committee formed at the eleventh hour to resist the working of the Act in London.
9. *National Medical Guild.*—Registered by a subcommittee of the London Medical Committee under the Trade Union Acts for the purpose of resisting further encroachments on the liberty of the profession. Membership panel and non-panel.
10. *Leicester Medical Union.*—A local trade union. The only other medical trade union in existence in this country besides the National Medical Guild.
11. *Non-panel Medical League.*—Arose during the Representative Meeting at Brighton in July, 1913, for the purpose of federating non-panel associations throughout the country. The executive of this body was objected to by certain non-panel men because many of its members were connected with the Council of the British Medical Association and other organisations. The Non-panel Medical League is now in a state of suspended animation in order to leave the field open to the National Medical Union which has taken on the function of coördinating non-panel views.
12. *Non-panel Committee of the British Medical Association.*—A recently formed committee with the object of focussing the views of non-panel members of the Association, and counterbalancing the proceedings of the Insurance Act Committee now concerned chiefly with panel questions.

This list leaves out of count the numerous local non-panel associations which exist throughout the country, the National Insurance Practitioners' Associations, and any other purely panel organisations which may exist, and also the Panel Committees formed under the Amending Act of 1913.

The present article deals chiefly with the formation and later development of the London Medical Committee, whose name and constitution have been considered by some to be quite irregular, but whose actions at all events were strenuous and virile.

Towards the end of 1912 the only way in which the British Medical Association showed any appreciation of the near approach of the actual working of medical benefit was in the suggestion made by the State Sickness Insurance Committee that a provisional medical committee should be formed in each insurance area. These committees had to be accessible, of course, to the entire profession, and not merely to the members of the British Medical Association. The suggested formation of these committees savoured a good deal of the pliable policy displayed throughout by the Council of the Association; but it was intended that they should become statutory committees *only in the event of the Act and regulations being rendered acceptable to the profession.* In the majority of insurance areas throughout the country these provisional medical committees were elected, consisting of members of the Association and of non-members; of practitioners in favour of the Act and of practitioners against it; and there is no doubt that they were extremely good and representative committees. After their formation these committees in many instances went to sleep; and the State Sickness Insurance Committee retired just before Christmas, 1912, to take a rest of two or three weeks, apparently quite oblivious of the fact that medical benefit would come into force on Jan. 15th, and that the profession had received no direction whatever how to meet the emergency.

The Provisional Medical Committee for the County of London was thoroughly representative. It was chosen according to borough areas, care being taken that every borough should have a representative, though the election itself was carried out through the divisions of the Association. The committee included consultants and members of hospital staffs, general practitioners of every shade of opinion, Poor-law medical officers, men who were in favour of the Act, practitioners in industrial areas who were strongly opposed to the Act, and men who never under any consideration whatever would find it necessary to go on the panel. Non-members of the British Medical Association were duly represented. Two days after Christmas the committee met for the first time, and it was plain from the outset that the temper of the great majority was strongly opposed to the working of the Act. It was from the uncompromising attitude of the great majority of the members of the Provisional Medical Committee for London that one of the most dramatic features of the struggle against the Insurance Act took its origin; for almost from the outset, and nearly three weeks before the pledge was removed b [illegible] Jan. 18th, the [illegible] formed itself in[illegible] Exception has been taken to this name as likely to be confused with the Statutory Medical Committee for the County of London, which even at the present moment is non-existent. But the representative character of the London Medical Committee at the time of its inception justified the use of this name, and it is claimed that the resulting inconvenience could not have been foretold.

The process of formation of the London Medical Committee may be described as follows. In the first place, the Provisional Medical Committee more or less retired into the background until it might happen to be needed. Next two or three members of the original committee who chanced to be supporters of the Act sent in their resignations, a course followed by a few other members. Then the new committee was, very early in its existence, strengthened by the addition of members of the Council of the British Medical Association, who represented the Metropolitan Counties Branch. At that time—three weeks before medical benefit came into force—the vast majority of London practitioners was strongly opposed to the Act, and gladly supported an organisation which looked like showing courage in the time of need.

One of the first acts of the London Medical Committee was to summon by telegram the State Sickness Insurance Committee, who appeared to be inclined at first to resent the activity urged upon them. For the wish of the London Medical Committee was to extend to the provinces the campaign suggested for London, and to endeavour even at the eleventh hour to induce the British Medical Association to take prominent action. After much debate the State Sickness Insurance Committee declined to take part in the campaign, but agreed to give its approval to the London Medical Committee opening offices and carrying on its propaganda from the headquarters of the Association.

It is asserted by some that the London Medical Committee had no legal existence, that it was a revolutionary committee, that it was there to resist the law. At any rate, it was the only body which made a determined effort to carry out the expressed desires of Representative Meeting after Representative Meeting of the British Medical Association, and of the majority of the medical profession so far as they were ascertainable at that time. And inasmuch as those who had authority did little or nothing, no one questioned those who did something, even though they had not authority.

The London Medical Committee soon began to make its mark. It met frequently, and its leaders spent nearly all their time at the offices at 429, Strand, organising and carrying on the business of the committee. The newspapers were filled with its doings or with information supplied by the committee. It urged the full application of Section 15 (3) of the Act, permitting insured persons to make their own arrangements. It held meetings of insured persons all over London, at which resolutions were passed with very little opposition demanding the right to contract out with the insured person's own doctor. The hoardings were placarded with posters and handbills were distributed; and as a result an enormous number of petitions were received by the London Insurance Committee from insured persons asking to be allowed to make their own arrangements for medical attendance.

The achievements of the committee soon began to be discussed in the House of Commons. Mr. Worthington Evans voiced their cause in the House by protesting that the authorities had interfered with the free choice of doctor, had prevented private arrangements being concluded, and had made "threats" to send men where doctors refused to serve on the panel and impose these strangers on the insured. Such threats had "poisoned the whole administration of the Act." Dr. C. Addison, taking the other side, described the London Medical Committee as "hot heads" who ignored the interests of the insured, prevented doctors from going on the panel, and had "set every public authority in the country against them." The greatest testimonial ever received by the London Medical Committee was probably when Dr. Addison stated that had it not been for that committee there would have been 1000 more practitioners on the London panel. Mr. Lloyd George spoke of doctors who put forward a "wild-cat" scheme. Thus it will be seen that the London Medical Committee early contrived to get excellent advertisement.

The committee organised several subcommittees to deal with different portions of its work; it gave a great deal of information and assistance to medical men in London; and it was responsible for a successful and well-arranged meeting in the Queen's Hall, under the chairmanship of Sir Thomas Crosby.

One of the subcommittees of the London Medical Committee was appointed for the purpose of considering the formation of a trade union. It was recognised that the constitution of the British Medical Association renders it unable to grapple successfully with emergencies as they arise, while the impossibility of setting its funds free from liability to attachment prevents any of its schemes for the formation of a special fund ever being established on a safe footing. When the actual fight was over many of the active participants turned their attention to the development of the National Medical Guild. Formed in March, 1913, by the members of the subcommittee, the guild was registered in July on the application of the 12 original members of its council. Originally the whole of the members of the subcommittee were non-panel men; but it was recognised that in any future fight that may occur no sectional body will have any chance of success, and that a trade union must contain within its ranks the majority of medical practitioners. Meanwhile, as this went on, and the strenuous fighting of early days became no longer possible, a divergence of opinion became apparent amongst the members of the London Medical Committee. This was a perfectly natural result when the cohesive effect of the first enthusiasm began to lose its power. The divergent lines of thought were represented on the one hand by those who considered that the ultimate success of the profession consists in an all-inclusive trade union under strong central management, and on the other by those who believed that united action by non-panel men in maintaining the old world view of the dignity of medical practice would sufficiently impress both the Government and the public to bring about a reversal of the system adopted under the Insurance Act. The former party is now represented by the National Medical Guild, the latter by the purely non-panel association the National Medical Union. To the latter what remains of the London Medical Committee is now federated; but inasmuch as local non-panel associations now exist in many parts of London, it is hardly likely that the London Medical Committee, somewhat changed in character, and possibly becoming superfluous, will prolong its activities for any length of time.

(To be continued.)

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

NEWCASTLE-ON-TYNE.

College of Medicine, Newcastle-on-Tyne.

THE annual meeting of the University of Durham College of Medicine was held on Feb. 11th in the college, Councillor W. J. Sanderson, chairman of the board of governors, presiding. Sir George Hare Philipson was unanimously re-elected vice-chairman of the governors, and Professor Rutherford Morison and Mr. Herbert Shaw (the Sheriff of Newcastle) were elected as representatives on the council of the college. The various reports were adopted. The finances showed that the receipts for the year amounted to £9518 and that the deficiency had been reduced by £189. The treasurer of the college, Mr. Cecil Cochrane, referred to the handsome legacy of £10,000 bequeathed to the college by the late Miss Easton, which would enable the authorities to free the college from the incubus in the way of mortgages on land and buildings under which it had laboured for many years. It was announced that arrangements had been made during the past year with the honorary medical and surgical staff of the Royal Victoria Infirmary, Newcastle-on-Tyne, regarding the clinical portion of the students' curriculum, and that the settlement had received the sanction of the Board of Education. The chief results of these arrangements were: (1) that the fees for clinical teaching are paid to the college, and the college is responsible for the payment of the clinical teachers; and (2) that the clinical teachers will elect two of their members to act on the college council.

Hospital Accommodation of Newcastle.

On Jan. 28th the Lord Mayor of Newcastle opened the first block of a new infirmary attached to the workhouse and formally handed over the building to the chairman of the board (Mr. Lonsdale). The latter stated that the whole scheme would consist of six blocks similar to that which was being opened, and would have nearly a thousand beds and an administrative block. The block which was opened is erected just north of the present workhouse buildings and faces south. The total accommodation provided is for 154 patients. It is built in two floors, the lower of which is to be used for general cases, while the second floor is for the treatment of incipient cases of phthisis. The total cost of the block is £21,587, including furnishings, which thus works out at about £133 per bed. The chairman of the board dealt with the hospital accommodation in Newcastle and district, and quoted the remarks of a Local Government Board inspector as to the excellent position which Newcastle occupied in comparison with other great cities. There are in Newcastle 19 hospitals, in addition to private hospitals and dispensaries, with accommodation for 2750 beds, which is approximately 1 per cent. of the population. Thirteen of these with 800 beds are supported by voluntary contributions; two with 150 beds are private institutions; two hospitals with 340 beds are maintained out of city rates; one with 900 beds is supported, eight-ninths out of poor rate, one-ninth out of city rate; and one hospital is maintained solely from the poor rate. Between £40,000 and £50,000 per year are paid out of the poor rate for the care and treatment of the sick poor in hospitals; and yet all this accommodation in and around Newcastle is far from sufficient to meet the needs. The Royal Victoria Infirmary, built only a few years ago, has been found to be too small, and the house committee are seriously contemplating great extensions. At the Infectious Hospital some £12,000 are shortly to be expended in providing more accommodation. At the Mental Hospital at Coxlodge further extensions are in operation which will cost about £25,000. The chairman concluded with a reference to the great increase made in the medical and nursing staffs during the last few years.

Feb. 17th.

WALES AND WESTERN COUNTIES.

Tuberculosis Scheme for Pembrokeshire.

EXCLUDING Pembrokeshire, all the county councils and county borough councils in Wales and Monmouthshire have handed over the administration of sanatorium benefit under the National Insurance Act to the Welsh National Memorial Association, the councils contributing to the funds of the association sums equal to a rate of ½*d.* in the £ in the respective districts. The Pembrokeshire county council, however, at its meeting on Feb. 3rd resolved, on the recommendation of the public health and housing committee, by 31 votes to 13, to submit to the Insurance Commissioners for Wales a separate scheme. The scheme contemplates the erection of a temporary hospital to accommodate 18 patients at a capital cost of £1700, the establishment of a central dispensary at Haverfordwest, and also of branch dispensaries at Cardigan, St. David's, Fishguard, Tenby, and Pembroke Dock, with five shelters for loan to patients; the administrative work to be carried out by the county medical officer of health with an assistant tuberculosis officer, who will be paid a salary. The estimated total cost of the scheme is £3303 per annum, which, when reduced by grants from the Insurance Committee, boards of guardians, and the Treasury, will amount to £1152, a sum about equal to a rate of ¾*d.* in the £ on the rateable value of the administrative county.

Cardiff Medical School.

The Cardiff Medical School has hitherto been housed in the old infirmary buildings in Newport-road, with the addition from time to time of various one-storey iron or wood annexes. This arrangement of the school buildings is far from what could be desired, though the teaching staff has readily submitted to the difficulties in anticipation of the erection of more complete buildings adjoining those of the University in Cathays Park. The complete scheme of the University buildings included medical school buildings, but lack of funds has hitherto stood in the way. In 1912, however, Sir James

Thomas offered to give 10,000 guineas towards the erection of a physiological department Eventually he increased this sum, provided the medical school buildings were erected on the site of the existing school, which has an area of nearly three acres and is quite close to the Cardiff Hospital The total cost of the new buildings is estimated at £90,000, and of this sum one third has been promised by Sir James Thomas and the remainder by an anonymous donor When the new buildings are completed a complete medical school in which the full five years curriculum can be taken will be available The clinical material in Cardiff is very varied, and is provided in the wards of the King Edward VII 's Hospital, the Seamen's Hospital, the Isolation Hospital, the Mental Hospital, and the Tuberculosis Sanatorium A deputation consisting of Lord Kenyon, Lord Merthyr, Colonel E M Bruce Vaughan, Dr Ewen J Maclean Sir Almroth Wright, and Professor D Hepburn, and introduced by Mr David Davies, M.P , to urge a Treasury grant for the maintenance of the school, was sympathetically received by the Chancellor of the Exchequer on Feb 12th

Welsh National Memorial Sanatorium

The Welsh National Memorial Association has already taken over one sanatorium in South Wales and another small one in North Wales It is the intention of the association to erect at least three other institutions, one in the north, one in the south, and the other in mid Wales That in South Wales is to be erected on a site of nearly 400 acres and will accommodate 250 adults and 54 children

Decrease of Vaccination in the West of England

At the last meeting of the St Thomas s (Devon) board of guardians it was shown that during the last six months 350 successful vaccinations had been performed and 142 conscientious exemptions granted, as compared with 420 vaccinations and 109 exemptions for the preceding six months Some of the members "deplored such an increase of exemptions

A Useful Charity

During 1913 13 patients in the last stage of illness were admitted to the Einsborough House Exeter The number of weeks spent in the home by these 13 patients was 397 at an average expenditure of 19*s* per patient The financial statement showed a small deficit It is hoped, through the generosity of Mrs Godfrey Walker, to purchase larger premises so as to admit 20 patients

Need of Isolation Hospitals in Cornwall

The medical officer of health for Liskeard, Cornwall, Mr W Nettle in his annual report for 1913 states that the provision of an isolation hospital for infectious diseases is urgently required The need of an isolation hospital is also urged by the medical officer of health for St Austell rural district council in his annual report

Feb 17th

IRELAND

Dinner of the Royal College of Surgeons

ON Feb 11th the Charter Day dinner of the Royal College of Surgeons of Ireland was held, the President, Mr R D Purefoy, being in the chair The Lord Lieutenant of Ireland accepted the invitation of the College to be present There was an exceptionally large attendance of Fellows and guests Speeches were made by the Lord Lieutenant, the President, the Vice President (Mr F Conway Dwyer), the Master of the Rolls, Dr. James Little, the Rev J P Mahaffy, and Sir Charles A Cameron At the close of the dinner the Lord Lieutenant on behalf of the Council, presented the President with a silver tray as a mark of recognition of the way in which he had performed the duties of his office At the same time he asked the President to accept for his sister, Miss Purefoy, a handsome pendant

The Rotunda Hospital

At the last meeting of the board of governors of the Rotunda Hospital Dr T P C Kirkpatrick was elected a governor in recognition of his eminent services to the hospital in writing its history[1] In the ordinary way governors are elected from those who have given to the funds of the hospital a sum of not less than £100, and it is very rarely that the board has exercised its power of electing a governor in recognition of "eminent services to the hospital "

The Friendly Societies in Limerick

For the past 15 months there has been a dispute between the medical profession of Limerick and the Friendly Societies operating there The medical men in the autumn of 1912 gave notice to terminate their agreements for medical attendance on members of Friendly Societies and their families At the same time they stated that they would be willing to give attendance at the rate of 8*s* 6*d* per member for attendance on the member alone or 12*s* for attendance on the member and his dependents The societies refused to accept these terms, and for more than a year it was found impossible to make any arrangement The societies have now capitulated, accepting the terms offered by the profession, and reappointing their former medical officers The medical men of Limerick are to be congratulated on the courage and determination with which they have stood together

Old age Pensions in Ireland

The following figures show the number of old age pensioners on March 31st, 1913, in the three kingdoms —

Country	Population 1911		Number of old age pensioners		Proportion of pensioners to 1000 of population
England and Wales	36 070 492	...	668 646	. .	18 5
Scotland	4,760 904	. .	96 239	. .	20 2
Ireland .	4 390 219	...	203 036	...	46 2
Total	45 221 615		967,921		21 4

In other words it appears that while in 1911 the population of Ireland was more than 370 000 less than that of Scotland Ireland on March 31st, 1913, had 106 800 more old age pensioners The average number of old age pensioners in the administrative counties of Ireland was 51 92 per 1000 of the population, ranging from 20 19 in Dublin County, to 70 02 in Leitrim County The population of Ulster was (in 1911) 1 581 696 the total number of old age pensioners 70 657, and the proportion to population 44 7 per 1000 With the exception of Dublin County (which is largely residential) Belfast City has the smallest number of old age pensioners in proportion to population of any scheduled area in Ireland

The Cottage Hospital, Coleraine

A two days' bazaar, having for its object the raising of £1000 or more to clear off an old debt and to defray the cost of recent renovations to the Cottage Hospital, Coleraine, was opened by Lady

---

[1] THE LANCET Feb 14th 1914 p 470

O'Neill in Coleraine on Feb. 11th. The effort is being warmly supported by all creeds and classes living in North Antrim and North and South Derry.

Poliomyelitis in Fermanagh.

Mr. Acheson Aiken, medical officer of Irvinestown dispensary district, co. Fermanagh, has reported a serious outbreak of poliomyelitis in his district, there being 12 cases under treatment. The onset of the disease in those affected was very sudden No cause for the outbreak can be given.

Feb. 17th.

PARIS.

Military Service and the Deaf.

Dr. Maurice, in a communication to the Société Médicale des Praticiens, calls attention to the serious losses sustained in recruiting for the army through the rejection of the deaf. According to the statistics of the Ministry for War 921 recruits are lost on account of deafness—viz., 510 exempt, 296 transferred to auxiliary service, and 115 rejected. The total deficit of the three classes means a total loss in the three years of service of 2763 young men, who but for their infirmity would form a fine regiment. Dr. Maurice's method of auditory re-education consists in subjecting the ear to the recurrence of sounds whose pitch, intensity, and timbre have been studiously selected for this end. The ear is educated to hear sounds varying from 80 to 5500 vibrations a second, a range adequate to include all the vibrations that the human larynx can emit. Very satisfactory results have thus been obtained. The disappearance of the tympanum and the ossicles is often compatible with a sufficient audition for military requirements. It would not be necessary to establish a special regiment with specialist medical officers in order to be able to enlist the deaf; it would suffice to begin by treating at the military school of Val de Grâce the 115 soldiers suffering from deafness who at the present time are actually enlisted yearly, kept awhile under observation, and finally discharged for physical incapacity. As these men are not infirm in the ordinary sense of the word, they could be made to work. Re-education could cure, or at any rate considerably ameliorate, their condition in from 25 to 60 days. If this plan proved successful the 510 exempts need no more be returned to their homes, for deafness would be no longer a cause for rejection. Formerly those with hernia were rejected wholesale. Now they are enlisted. It is true they cannot be compelled to submit to operation, but they have either to undergo service as they are, or to be operated on; and the suffering leads them to submit to an operation which can hardly be considered dangerous. The deaf would be subject only to the same lot; indeed, their position would be even better, since in their case there is usually no question of operation.

A Proposed Ministry of Public Health.

The serious discussions in regard to leprosy which are taking place at present between the medical profession and the public health authorities have drawn attention to the question of centralising in a single service, with the title of Ministry of Public Health, all the departments dealing with hygiene, which are now scattered among different ministerial departments under conditions that materially impede their working. Hygienic functions, in point of fact, are to be found being discharged by most of the Ministries. The Ministry of the Interior controls matters relating to the Assistance Publique, the hospitals, the prevention of epidemics, and the hygienic staff. The hygiene of emigrants is under the Ministry of Commerce. Adulteration and food hygiene are controlled by the Ministry of Finance. Medical congresses are under the Ministry of Public Instruction. Legal medicine is controlled by the Ministry of Justice. Epizootics and the prevention of diseases transmissible by animals, such as glanders and anthrax, come under the Ministry of Agriculture; while international sanitary regulations are in the province of the Ministry of Foreign Affairs, not to mention the special sanitary organisations established by the Army, Navy, and Colonial Departments. Some years ago Senator Strauss showed the necessity for uniting all the organisations into one service. M. Mirman has now advocated this redistribution of the services, which would entail no new expense, but simply a closer centralisation. Not all medical men favour this plan, however, for many think it would result in an officialisation of medicine, which would materially hamper the independence of the profession.

The Electrical Conductivity of Blood Serum.

Professor Widal and his assistant, Dr. Javal, whose work in regard to chloride and nitrogen retention is well known, have brought before the Académie des Sciences a mode of estimating the chloride retention in blood serum and organic fluids. This method, added to chemical analysis and cryoscopy, gives valuable information on the variation of chlorides in different subjects and in the same subject, or in the course of the same disease. The method of electrical resistance makes it possible to determine variations of great importance amounting to as much sometimes as a gramme to the litre. The method can be very easily and rapidly practised.

Death of M. Bertillon.

The death of M. Bertillon from anæmia occurred at Paris on Feb. 13th. M. Bertillon, though not a medical man, was the son, grandson, and brother of medical men, and his own studies in the use of anthropometry as a means of identifying criminals closely allied him to medicine. He was born in Paris in 1853, and was head of the identification department in the Prefecture of Police of Paris.

Feb. 16th.

VIENNA.

Public Health Statistics for December, 1914.

THE exceptionally warm and dry weather which prevailed in this city during the last month of 1913 is acknowledged to have been the cause of a very favourable condition of the public health, as observed in the report of the Board of Health. During this month 2320 persons died, being a mortality-rate of 13 per 1000 inhabitants, and there were 2690 births of living children, with 280 still-births. There was not a single fatal case of typhoid fever, cholera, or measles, but there were 20 deaths due to scarlet fever, 17 to whooping-cough, 28 to diphtheria, 406 to tuberculosis, 4 to erysipelas, and 216 to neoplasmata. An isolated outbreak of small-pox which occurred in January is mentioned in a separate paragraph. The following cases of disease were reported under the Notification of Infectious Diseases Act. Puerperal fever, 4; scarlet fever, 250; diphtheria, 251; trachoma, 4; epidemic poliomyelitis, 1; influenza, 2; and typhoid fever, 3. The month was characterised by an absence of severe pulmonary and bronchial diseases and a marked decline in the infant mortality, whilst the duration of sunshine observed in Vienna was 109 hours, an amount far in excess of the average figure.

Small-pox in Vienna.

Small-pox, that former scourge of Europe, is so uncommon in this city that much interest has been aroused by the recent appearance of six isolated cases. A few weeks ago a man engaged in the delivery of bread to customers' houses became ill, and as the nature of his disease was not recognised at once he was permitted to follow his occupation, although mature pustules were visible on his face. When the diagnosis of small-pox was eventually made he had already infected his wife and his son, a boy of 4 years of age. Three other persons were also attacked, but owing to the very complete prophylactic and disinfectant precautions taken by the authorities of the Board of Health the outbreak was suppressed. The boy mentioned above died from angina, complicated with cardiac paralysis. The fact that the older patient could walk about without trouble, and that his illness was not recognised at first, is a proof how rare, and therefore how comparatively unknown, small-pox is now in this country. It is chiefly due to the extensive vaccination of the people which has reached a very high degree here. Although there is no actual compulsion for the general population, candidates for nearly all appointments, both public and private, as well as for municipal or State service, have to be vaccinated, and it may be safely said that in Vienna over 99 per cent. of the population have been vaccinated at least once. When there was a small-pox scare a few years ago it was found that those who had for some reason or other neglected this precaution were very willing to have the operation performed notwithstanding the slight interference with their general health.

Alteration of the Height Standard for the Austro-Hungarian Army and Navy.

Under the new law recruits for the Austro-Hungarian army and navy must have a height of at least 152 centimetres (5 feet), whilst those recruits who will have to work as artisans or at some trade in the army or navy, or as clerks in offices, may be accepted if their height is not less than 150 centimetres (4 feet 11 inches). The old law required a minimum height of 5 feet 1 inch for ordinary soldiers or sailors, whilst the artisans or tradesmen could be recruited without any regard being paid to their height. This departure from the old standard has been introduced on account of the necessity for obtaining a larger number of soldiers fit for work and service under the increased military precautions which have been taken in this country during the last 12 months. It has been noted that a considerable percentage of recruits had to be rejected, especially among those coming from certain poor districts, where the people are underfed, owing to the height-limit not being reached, although otherwise they were quite fit for service and willing to become soldiers. At present not even 1 per cent. of our population is required for military service in time of peace, whilst in other countries—such as Germany, France, and Italy—over 1·5 per cent. have to serve annually with the colours. It may be noted that the Austrian standard is higher than the French one, which goes below the 150 centimetres.

Feb 16th.

INDIA.

The All-India Sanitary Conference.

THE provisional programme of the All-India Sanitary Conference at Lucknow shows that the members will have a very busy time. On the first day there will be the opening address by Sir H. Butler. Papers on milk standards and the milk trade will be furnished by several medical men, and municipal drainage will be discussed. The early morning of the second day will be devoted to an inspection of the sanitation and improvements of Lucknow, and after breakfast there will be the opening address in the Research Section by Sir C. P. Lukis, Director-General, Indian Medical Service, the remainder of the day being given over to papers on malaria by Lieutenant Doctor Froilano de Mello (of Goa), Sir Ronald Ross, Major S. R. Christophers, Major E. L. Perry, Major J. L. Marjoribanks, Dr. W. R. Macdonald, and Dr. C. A. Bentley. In the evening there will be popular lectures on goitre by Major R. McCarrison and on malaria by Major Christophers. On the 21st reports on town planning and papers on mosquitoes and kala-azar will be communicated. On the 22nd there will be a visit of inspection to Benares, and the 23rd will be devoted to infantile mortality, notification of disease, tuberculosis, water-supply, rural sanitation, the medical inspection of schools, and the teaching of hygiene. On the 24th certain phases of plague infection will be discussed by Captain J. C. G. Kunhardt, Colonel S. Browning Smith, Major W. Glen Liston, and Captain Taylor, and vital statistics by Dr. Bentley and Captain T. C. McC. Young. On the 26th notes will be read on the bacteriology of water by Dr. Hirst, and on the filtration of water by Mr. Hutton and Captain J. Morison. On the 27th the resolutions of the conference will be considered and passed.

Women's Medical Service for India.

The following *communiqué* has been issued by the office of the Central Committee, Countess of Dufferin's Fund:—

> *Women's Medical Service for India.*—The lady doctors whose names have been recently published as having been selected for the Women's Medical Service for India have been chosen by the lady President, Her Excellency Lady Hardinge, and the Central Committee of the Dufferin Fund, either on account of their previous good services under the Dufferin Fund, or of their special qualifications and testimonials. This women service is fixed at a maximum of 25 ladies. Of the 24 at present selected, 18 are Europeans or Anglo-Indians and 6 are Indians. Two of these latter, however, have since intimated their inability to join the service.

It will be noticed that it has been found unnecessary at the outset to recruit directly from England for the first appointments to the service, and judging from the number of applications received, and the increasing supply of medical women in India, it seems likely that the appointments will generally be made from among ladies in this country.

Obituary.

THEODORE MAXWELL, B.A., M.D. CANTAB., B.SC. LOND., F.R.C.S. EDIN., D.P.H., F.C.S.

WE regret to record the death early on the morning of Feb. 13th, after a short illness, of Dr. Theodore Maxwell, for many years a valued contributor to the columns of THE LANCET.

Theodore Maxwell was born at Barnsley, Yorks, on March 29th, 1847. His parents were the Rev. Edward Maxwell, M.A., and Mary Hogg Nicholson Maxwell, sister of General John Nicholson, who was killed at Delhi in 1857. He received his early education at Felstead School and privately at Enfield and Blackheath. He then entered at University College, London, where he took the gold medal for chemistry. In October, 1866, he went to King's College, Cambridge, and whilst in residence there he obtained the B.Sc. degree of the University of London. In 1870 he graduated B.A. with honours in the Natural Science tripos at Cambridge, and took the M.B. degree two years later, proceeding to the doctorate in 1876. In 1873 he obtained the Fellowship of the Royal College of Surgeons of Edinburgh.

During the Franco-Prussian war Maxwell joined the Belgian ambulance detachment and was in Sedan the day after the battle. He and a fellow medical student escorted a French lady to her home in Orleans during the war, and he wrote a series of letters which was printed in various papers.

During 1873 he was attached to the Edinburgh Medical Mission until September, when he married Elizabeth Eyre Ashby, daughter of the late Dr. J. E. Ashby, of Enfield, at whose school he had been as a boy. He and his wife immediately sailed for India. In the following April they went to Kashmir, where he hoped to build a hospital and act as a medical missionary. The Maharajah of Kashmir gave him a piece of land for the hospital in the town of Srinagar, and Dr. Maxwell performed a large number of eye and other operations in Srinagar. But in the autumn of 1875 his health broke down, and he was ordered to England and forbidden to return. For three years he practised at Hanwell. In 1879 he and Mrs. Maxwell went to Vienna, where he studied special subjects at the Kinia Hospital under Professor Schröter and others. He then returned to England and began practice in Woolwich, where he at once identified himself with many sides of public life. He worked hard at creating an interest in missions in Woolwich, and established and was president of the Woolwich, Charlton, and Plumstead Missionary Association. He became lay reader for the diocese, and attended the ruridecanal meetings. He was a constant attendant at St. John's Church, Woolwich, to which he gave an organ. After his retirement from practice in 1908 he took up amateur typography, and devoted himself to printing Scripture texts, &c., in Hebrew, Servian, Bulgarian, and other languages. His enthusiasm may be judged from the fact that he sent out over 10,000 Christmas cards with texts for distribution amongst the troops engaged in the Balkan war.

Dr. Maxwell will be remembered by all who came in touch with him as a man of singularly high character—zealous, learned, and industrious. His chief literary work was typical of his mind and disposition. This was the "Terminologia Medica Polyglotta: a Concise International Dictionary of Medical Terms," published in 1890, which set out by an ingenious device the medical synonyms of seven European languages within a compass of 460 pages.

EDWARD SKINNER, M.R.C.S. ENG., L.R.C.P. EDIN., L.S.A.,

LECTURER ON OSTEOLOGY IN THE UNIVERSITY OF SHEFFIELD.

IN the death of Mr. Edward Skinner, on Feb. 11th, the medical profession of Sheffield loses a familiar figure and a respected colleague. His family has for many years been associated locally with things medical, his father and elder brother, both of whom predeceased him, having been medical men. For over 40 years Mr. Skinner was actively engaged in a large general practice, but in spite of the heavy calls which this involved he took a deep and practical interest in the School of Medicine at a time when such help was sorely needed. It was in the "seventies" that he became lecturer on anatomy, a post which his father had held before him, and from then up to 1897, when with the foundation of the University College a chair of anatomy was formed, he rendered invaluable services. He also held the Government licence for practical anatomy, involving a great deal of responsible and often anxious work in connexion with the obtaining of subjects for dissection. From then onwards, until shortly before his death, he continued his active connexion with the anatomical department of University College, and later of the University, as lecturer on osteology. Nor was his interest in the Medical School confined to teaching; he was a regular attendant at all meetings connected with the management of its affairs. Of a peculiarly unselfish, contented, and gentle disposition, he will be greatly missed by a large circle of patients and personal friends, and many of the poorer classes lose in him one who performed many charitable acts in the course of his daily work. Owing to failing health he was compelled to retire from practice for a few years before his death. He leaves three sons, one of whom, Dr. E. F. Skinner, is dermatologist to the Royal Hospital, Sheffield, whilst another, Mr. W. F. Skinner, succeeds his father and his grandfather in the medical practice.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At an ordinary meeting of the society at 11, Chandos-street, Cavendish-square, London, W., this evening (Friday), at 8.30 P.M., a paper on Recent Research relating to Mediterranean Fever will be read by Fleet-Surgeon P. W. Bassett-Smith, who will also show specimens illustrating Barton's bodies and the other blood changes in Oroya fever.

ROYAL MATERNITY CHARITY OF LONDON.—The report of this charity for the year 1913 shows that of 855 cases delivered there was only one death. The number of infants born was 879, which includes 24 twin cases. Of infant deaths there were 12, and stillbirths 29. The ages of the mothers ranged from 18 to 48. The number of cases attended shows a reduction as compared with previous years, which the report points out is directly attributable to the National Insurance Act, though it is gratifying to note that the lesser number attended consisted of more deserving cases—viz., those left outside the maternity benefits accorded to those in employment. "This is one of the anomalies of the Act, that those *in* employment, with stamped cards, receive the maternity benefit of 30*s*., whilst those *out* of employment, casual labourers' wives, street hawkers, and such like, get no aid from the State, and still have to look to this and similar institutions to help them through their time of trouble." The balance sheet indicates that there is a sum of £4429 due to the bank. The address of the society is 31, Finsbury-square, London, E.C.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF INCIPIENT AND UNCONFIRMED INSANITY.

To the Editor of THE LANCET.

SIR,—In your leading article on this subject in THE LANCET of Feb. 7th I fear that you have unintentionally misinterpreted the position taken up by Dr. Hubert Bond. I did not understand Dr. Bond to express antagonism to the proposed change, but only to point out the difficulties in carrying out the proposed treatment arising from the existing state of the law.

The clauses providing for treatment without certificates, introduced by the late Lord Chancellor in his Lunacy Bills (1900 *et seq.*), had certainly been submitted to and received the approval of the Lunacy Commission, and that favourable view of the subject I feel sure has not varied during the past ten years.

The Commissioners from their official position cannot themselves enter into a discussion of this kind, and I trust, therefore, that you will kindly allow me this small space to point out a misapprehension which I am assured that you, Sir, would be the first to wish to remove.

I am, Sir, yours faithfully,

Feb. 16th, 1914. HENRY RAYNER.

⁂ Our leading article said that Dr. Hubert Bond declined to accept the proposition that modification of the law was desirable or that an immediate alteration upon the lines proposed was an essential condition of reform. Our attention has been called to the following passage in Dr. Bond's paper, which sufficiently shows that we were in error as to Dr. Bond's views:—

> It therefore becomes our duty, as practical men and women, to collaborate with the object of ascertaining how far we may seek to remove those legal formalities which, in the eyes of relatives of patients, rightly or wrongly, spell publicity and stigma, but without endangering the real interests of the patients or public safety. ...... Nevertheless, I am strongly of opinion that, if we are ever to secure promptness in treatment and an abolition of methods we all deplore, legislation is both desirable and necessary, as well with a view to the removal of some of the obnoxious formalities as in deference to the sentiments of relatives and those of the patients themselves.

We publish Dr. Rayner's letter and this acknowledgment of our misconception with pleasure —ED. L.

THE DEPENDENCE OF LEPROSY ON FISH EATING.

To the Editor of THE LANCET.

SIR,—In an annotation contained in THE LANCET of Dec. 13th, 1913, with the above title, reference is made to the transmission experiments carried out by Couret on cold-blooded animals, the accuracy of which it is stated has been confirmed by Dr. A. J. Smith, Dr. K. M. Lynch, and Dr. D. Rivas. In the account of Couret's experiments published in the *Journal of Experimental Medicine* (vol. xiii., p. 576), the writer states at the outset that his experiments were made with a culture of the bacillus lepræ which had been prepared by Duval, but on p. 582 he describes two experiments with leper tissue carried out on gold fish.

At the Seventeenth International Congress of Medicine in London Duval stated that he had been led into error, and that the cultures which he had previously claimed to be those of the bacillus lepræ were in reality neither cultures nor derivatives of that organism. The methods by which Duval in various publications claimed to have cultivated the bacillus lepræ were employed in this institute, and no cultures of any organisms were obtained for which it might be claimed that they had even a remote genetic relationship with the bacillus lepræ.

Duval, therefore, on his own admission, must have been working with contaminators, and Couret's experiments, other than the two referred to, were not carried out with the bacillus lepræ. As regards the two gold fish fed on teased nodules of leper tissue, and in which he claims to have found "in the omentum and other organs a few scattered acid-fast bacilli," those familiar with the subject will recognise that no value can be attached to such findings.

We are, Sir, yours faithfully,

H. FRASER.
W. FLETCHER.

Institute for Medical Research, Kuala Lumpur, Federated Malay States, Jan. 22nd, 1914.

THE RÔLE OF SYPHILIS IN MENTAL DEFICIENCY AND EPILEPSY.

To the Editor of THE LANCET.

SIR,—In an annotation on the above subject, appearing in your issue of Feb. 14th, you state, in connexion with the application of the Wassermann reaction to cases of mental deficiency, that you believe Dr. K. Frazer and Dr. H. F. Watson to be the first to carry out a general systematic inquiry on this subject in this country.

I would remind you that I carried out a similar investigation on 400 cases under the care of the Metropolitan Asylums Board, the results of which you were good enough to publish in your issue of Sept. 20th, 1913.

I am, Sir, yours faithfully,

J. LESLIE GORDON.

Fountain Temporary Asylum, Tooting, S.W., Feb. 14th, 1914.

⁂ We much regret the oversight —ED. L.

JENNERIAN VACCINATION.

To the Editor of THE LANCET.

SIR,—The letter of Dr. W. d'Este Emery in your issue of Feb. 14th concludes with the sentences: "We have a method which is tolerably efficacious in the prevention of small-pox, although our knowledge of the organism which causes that disease is singularly deficient." To know any means of preventing a terrible disease gives us as a profession a natural pride, but this pride is discounted by the admission of ignorance of the exact nature of the material we use to attain this great end. What steps are bacteriologists taking to remove this ignorance of an organism which in its modified form is an article of daily commerce? To prove that I do not undervalue Jennerian vaccination I may mention that some 22 years ago before going to collect material from patients at a small-pox hospital I revaccinated myself. Observations made about that time by others and myself enabled me to conclude that the causal agent of small-pox and vaccinia is a protozoon. It would not be amiss if every one of us set apart, say, one day each month to ask ourselves serious questions about pathology. Among such queries might well be one as to whether we are sure that the descendants of the tamed parasites of small-pox may not live in some of us and be capable of causing disease many years after they have left their valued little scars.

I am, Sir, yours faithfully,

Portland-place, W., Feb. 14th, 1914. J. JACKSON CLARKE.

THE TUNING-FORK AS AN AID TO DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—When a student in Glasgow my teachers demonstrated its use to the students as an aid in surgical as well as medical cases. This was some 14 years ago, perhaps a little more.

I am, Sir, yours faithfully,

Doncaster, Feb. 16th, 1914. T. L. ASHFORTH.

EXPERIMENTAL SYPHILIS ON MONKEYS.

To the Editor of THE LANCET.

SIR,—I shall be much obliged if either you or some of your readers can enlighten me upon a point connected with the above subject. About 1906 Metchnikoff and Roux inoculated some monkeys with syphilis. Were any of the sores—primary or secondary—examined for the spirochætæ, and was the blood of those animals examined for the Wassermann reaction and with what result?

I am, Sir, yours faithfully,

Liverpool, Feb. 15th, 1914. ROBT. R. RENTOUL.

A NATIONAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Asked how it is possible to combine the principle of a whole-time salaried service with free choice of doctor, Mr. Parker says: "I can see no reason why the present system of allotting patients should be discontinued if to-morrow the 20,000 panel doctors became whole-time salaried officers under the State." But surely there is the essential reason that under the present system a man can by refusal to accept patients, or by making himself so inaccessible or disagreeable that few desire to choose him, limit the size of his list almost indefinitely. If he does so, of course he also limits his remuneration, and that is his own affair. But such a privilege could not possibly be accorded to a man with a fixed salary. Whoever offers or pays the salary must see to it that a responsibility commensurate with the salary is accepted and met. It almost seems as if Mr. Parker must be using the words "free choice of doctor" in some different sense from that generally understood by the profession and by those of his colleagues in the State Medical Service Association who are so strongly opposed to the principle. These opponents of "free choice" say that it "makes the doctor conformable to the wishes of the patient" or "places the doctor under the control of the patient," or "makes the doctor regard the interests of his patient and disregard the pecuniary interest of his Approved Society." Many of us think that in the interest of the health of the nation all these conditions are preferable to those which would obtain under a whole-time salaried service. But we cannot understand how it is that at the same time some members of his association are calling out for a whole-time salaried service in order to save us from what they regard as these dangers of free choice of doctor, whilst Mr. Parker himself is asserting that all the advantages of "free choice," such as they are, can be secured in connexion with a whole-time salaried service. One or the other must surely be wrong. I cannot help thinking it is Mr. Parker, and would ask him to reconsider his position and endeavour, since he sees no serious dangers in free choice, to persuade his association to build their national service on the basis of a panel system with free choice of doctor. The foundations are already laid. No uprooting process is necessary. The profession need not be divided into doctors of the rich and doctors of the poor. The fair visions that Mr. Parker has seen of the linking up of hospital work and general practice, and the extension of medical aid to every individual who needs it, might thus possibly become realities whilst some of us are still alive. Before the task of transforming the medical profession into a salaried branch of the Civil Service the boldest reformer might hesitate.—I am, Sir, yours faithfully,

Harley-street, W., Feb. 15th, 1914. LAURISTON E. SHAW.

To the Editor of THE LANCET.

SIR,—If Mr. Parker imagines he has solved the problem of "free choice of doctor" as applied to a State Medical Service, few of your readers will share his opinion. To many it will appear that he does not himself see the difficulties to be encountered. Suppose "20,000 panel doctors became whole-time salaried officers under the State. At first there would be discrepancies with regard to the number on each doctor's list, but things would soon adjust themselves to the altered circumstances." Are all these 20,000 panel doctors in his proposed State service to be paid uniform salaries, as is usual in a Government service, or are their salaries to be according to the number of panel patients they each bring with them? Then as "things adjust themselves to the altered circumstances," is the State to make a revision of the salary each year, in the hope that when the adjustment is finally reached a uniform salary may be possible? Mr. Parker may consider such a service "analogous" to a State service, but it might also be described as the present panel system under State protection, and it might possess considerable advantages for some practitioners not possessed by a real State service. A panel doctor entering the Government service under such conditions might naturally expect that his salary should not be less than he already has from his panel patients. He would also be entitled to fair compensation for other professional emoluments he was required to resign. This might be good business for a few practitioners with a large panel, who might be enabled to draw the same salary without half the worries and anxieties which belong to them at the present time. But it is only a minority that have large panel practices, and the great majority would have to exist on an exceedingly moderate salary "while things were adjusting themselves," looking out for the crumbs that fell from the tables of their more fortunate brethren—i.e., the number over 3000—that might be compelled to select one of them. Perhaps it is wrong to say "compelled," for these patients, Mr. Parker says, have really as much "free choice" as they have at present, and the "free choice" is only taken away from the doctor, who might be willing to attend more than 3000. He is in error as to Poor-law patients lacking "free choice" at the present time. They already possess a "free choice" analogous to this. There are not a few instances that might be given of Poor-law patients moving into another district in order to get the services of the doctor of that particular district, a procedure which does not involve much difficulty to patients of that class. Like reformers of his kind, Mr. Parker has not the slightest regard for vested interests. He does not consider in the least the present purchase value of medical practices, as ordinary business enterprises. Any such change as he suggests would, no doubt, reduce these values to zero, and possibly for that reason he may think that their possessors are not entitled to compensation, but he will hardly persuade the latter of the equity of such a course.

In conclusion, he draws a highly coloured picture of the result to be obtained at the end of the journey, but the road thereto still remains as obscure as ever, the rivers to be crossed as unfordable, the mountains as impassable. The aeroplane by means of which he proposes to soar over all these difficulties is one such as, in my opinion, no Government that has any regard for its well-being is likely to trust itself to.

I am, Sir, yours faithfully,

Hackney road, N.E., Feb. 14th, 1914. MAJOR GREENWOOD.

MOSQUITO NETS.

To the Editor of THE LANCET.

SIR,—I notice that in your review on the Health of the Army in 1912 in THE LANCET of Feb. 14th you draw attention to the refusal of the Government of India to provide anti-mosquito nets for the protection of the British soldier against malaria. You deplore their policy, and say "it is extremely regrettable that such an obscurantist and short-sighted attitude should be adopted by the Indian Government."

I desire to point out that there is some excuse for the Indian Government's attitude so strongly criticised by you. I have served for the last five years in a well-known malarious station in the Punjab and have doctored Thomas Atkins through five corresponding malarial seasons. The latter are, throughout the Punjab, chiefly confined to the damp, hot, muggy weather of the rains, roughly July to October. During this period evaporation from the surface of the body is almost *nil*. The men lie naked on their beds at night with towels about their waists and depend for their sleep on the small current of air caused by a gently flapping punkha; the draught from the latter can be increased by lowering it or attaching towels so as to bring the flapping edge as close to the body as possible. The legs and arms of the sleeper are usually outstretched beyond the radius of the breeze, and therefore are the parts chiefly attacked by the mosquito. Should the punkha stop, the feeling of suffocation and intense heat soon awakens the man below. In place of the palliative punkha it is suggested that the soldier be offered a coarse-meshed mosquito curtain through which no air short of a hurricane can penetrate and over which the punkha cannot be pulled.

Inside a curtain on an ordinary hot night the occupant drips with perspiration and kicks, sleepless, from side to side, craving for slumber but finding only increasing prickly heat and suffocation. The only possible way a curtain can be tolerated is out in the open air or in the outside verandah of the barrack-room; even that is but little better—the heavy damp air clogging up the interstices completely prevents all entrance of air and at the same time drips through from above. Is it to be wondered that the men finally throw aside the whole erection and chance malaria. I personally was fortunate in the possession of an expensive, well-made, and fine-meshed mosquito curtain, supplemented by a Jost revolving air fan, yet often the feeling of intense suffocation has come over me, causing me to lift my curtains, knowing the risks, but taking them gladly.

Taking into consideration the doubtful success of such an experiment as the wholesale provision of mosquito nets for the troops, owing to the personal factor, I do not consider the Indian Government would be justified in undertaking the huge outlay and recurring charge involved. The cost of each mosquito curtain is about half a guinea and its life in the barrack room at the most one season. Fortunately, a possible remedy is coming more and more within the bounds of practical application. I refer to the substitution of large electric fans for the present unsatisfactory punkhas; these will not only cool the air but also keep away all mosquitoes by their draught, and when introduced into barrack rooms will solve one of the greatest problems in the prevention of malaria. I am, Sir, yours faithfully,

Feb. 17th, 1914. W. E. C. L.

THE NATIONAL INSURANCE ACT.

"OWN ARRANGEMENTS."

WE published last week the memorandum issued by the National Insurance Commissioners (England) dealing with the private arrangements which can be made by insured persons in respect of medical benefit. It is, of course, especially with regard to the possibility that an Insurance Committee may give permission to insured persons to make arrangements with people possessing no medical qualification that the memorandum will be scrutinised, and our readers may be informed that the whole matter has been, and still is, under the careful consideration of the General Medical Council. It has long been known that the National Insurance Act did give opportunity for insured persons to avail themselves of the services of individuals purporting to give medical benefit but devoid of medical qualification. The position, though so serious, has alleviating features. It was felt that Approved Societies would be very unwilling to pay away their funds in return for "medical" benefit given by persons who were not medical men, and this has proved to be the case. The general belief has been verified also that Insurance Committees would require evidence of the administration of medical treatment in accordance with the whole spirit of the Act—i.e., treatment rendered by qualified medical men. The example of the Worcester City Insurance Committee in sanctioning the treatment of insured persons by a herbalist[1] is not likely to be followed. Nor is that committee, in view of the revelations which took place at a recent inquest (see p. 561), likely to be embarrassed by many further requests from insured persons anxious to make private arrangements with Mr. Burden, the that office he made public his approval of the objects for which the society was founded.

---

[1] THE LANCET, Nov. 8th, 1913, p. 1359.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—The tenth annual meeting of this association will be held, by permission of Mrs. Charles Ebden, at 16, Draycott-place, Brompton, S.W., on Friday, March 6th, at 3.30 P.M., when the chair will be taken by the Duchess of Montrose. A short address on Midwifery in the Provinces will be delivered by Dr. George Reid, county medical officer for Staffordshire.

ROYAL DEVON AND EXETER HOSPITAL.—Mr. Harry Hems, of Exeter, has given a polished alabaster reredos to the chapel of St. Luke attached to the Royal Devon and Exeter Hospital. Mr. Hems is a member of the committee of the charity, with which he has been connected for about 50 years. The chapel was erected at a cost of £3000 by the late Mr. Arthur Kempe, honorary surgeon to the charity, in 1869.

BY the death of Mr. Robert Clay Sudlow, from heart failure following an attack of bronchitis, a well-known figure will be missed from wholesale pharmaceutical commerce. Mr. Sudlow, who died on Feb. 17th, at the age of 68, was for 25 years general manager of Messrs. Burroughs, Wellcome, and Co., resigning about ten years ago owing to failure of health. Mr. Sudlow was well known in Masonic circles.

ELECTRICALLY STERILISED MILK.—The Liverpool corporation is now sterilising by electricity the infants' milk supplied to the public from the various corporation milk depôts in that city. All tuberculous and manurial contamination is said to be removed, as well as danger from zymotic disease. If the taste and chemistry of the milk remain unaltered by this form of sterilisation, as is alleged, it will become necessary for other corporations to look into the matter.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—A council meeting was held at 34, Copthall-avenue, E.C., on Feb. 10th, Surgeon-General G. J. H. Evatt, the President, being in the chair. Dr. Major Greenwood, honorary secretary, reported that the Burnley dispute[1] had not yet been settled. The matter had been referred to a committee consisting of representatives of the local profession and of the guardians in equal numbers, with the district inspector of the Local Government Board as chairman, but so far no agreement had been come to. The honorary secretary reported that he had done his utmost at the recent Representative Meeting of the British Medical Association in London to prevent the rescinding of the latter portion of the resolution condemning the surrender of panel fees by Poor-law medical officers passed at the Brighton meeting of the British Medical Association, but had failed, so that that resolution had been considerably watered down. The council expressed much regret that this had been done. A letter from the secretary of the National Poor-law Officers' Association desiring to know whether their association approved of the federation of all sectional Poor-law Officers' Associations was considered. The honorary secretary explained that since the last council meeting a meeting of representatives of all branches of the Poor-law had been held at Norfolk House, Strand, and a resolution had been almost unanimously carried in favour of such federation. After discussion, the principle of federation was unanimously approved by the council, but doubt was expressed as to whether the funds of the association could afford the necessary extra payments. The honorary secretary then read a letter from the Mayor of Burnley inviting the association to hold their annual meeting this year at Burnley, and it was decided that Thursday, July 2nd, should be selected as the day for the meeting. The council then considered the recent Poor-law Institutions' Order, 1913, to come into force on April 1st next, which will no doubt seriously affect many of their indoor members. The addition to their duties was very considerable, and there was no mention in the Order of any extra payment for the extra work. The honorary secretary pointed out that before they could give any effective assistance they must be in possession of the facts of the case. The council decided that it would be advisable to draw up a report on the Order and its effect on the duties of the medical officers of Poor-law institutions. This was left in the hands of the honorary secretary and Dr. C. Thackray Parsons. The honorary secretary drew attention to an error that was widely prevalent among the Poor-law Medical Service that their association was only for outdoor Poor-law medical officers. He thought every effort should be made to dissipate that erroneous impression.

PRESENTATIONS TO A MEDICAL MAN.—At the Wilts County Asylum recently Mr. John Ireland Bowes, M.R.C.S. Eng., L.S.A., who has just resigned the appointment of medical superintendent after nearly 40 years' service, was the recipient of several presentations. The male patients presented him with a silver-mounted walking-stick and the female patients with a silver-mounted briar pipe. The resident staff gave Mr. Bowes a set of solid silver candelabra. The presentations were made by the newly appointed successor to Mr. Bowes, Dr. S. J. Cole, who was formerly senior assistant medical officer of the institution for about nine years.

DONATIONS AND BEQUESTS.—The late Major G. H. Brand left by will £1000 to St. Mary's Hospital for a "Major Brand bed."—Subject to his wife's life interest the late Mr. George Day, of St. Michael, Somerset, has left the income of a house and farm of about 117 acres upon trust for Taunton Hospital.—The late Mr. R. E. Watmore has, among other bequests, left £500 each to the following institutions: Friedenheim Hospital for the Dying, Brompton Hospital, British Home and Hospital for Incurables at Streatham, and the Royal Association in Aid of the Deaf and Dumb.—By the will of the late Mr. Alexander Allan, of Aberdeen, there were left, among other bequests, £10,000 to the Aberdeen Royal Infirmary, £5000 to the Aberdeen Royal Sick Children's Hospital, £4000 to the Morningfield Hospital, Aberdeen, and £2000 to the Aberdeen Convalescent Hospital. The residue of the estate will also be divided among these and other charities.

BRITISH DENTAL ASSOCIATION: THE SMITH TURNER SCHOLARSHIP IN DENTAL MECHANICS.—This scholarship, of the annual value of £30, is founded to do honour to the memory of James Smith Turner, while helping those dental students who have financial difficulty in completing the dental curriculum. The scholarship is open to any registered dental student who has not completed the curriculum required for a dental qualification, and is awarded after examination, being tenable for one or two years, at the discretion of the Fund Committee. The scholarship money will be paid to a dental or a medical school in Great Britain or Ireland, approved by the committee, in discharge of fees for any portion of the dental curriculum. The examination is both practical and *vivâ voce*. The next examination will be held during April, 1914, at a dental school and on a date to be announced later. Applications must be received on or before March 15th, addressed to the Secretary, British Dental Association, 19, Hanover-square, London, W. Printed forms for applications will be supplied to candidates.

ROYAL SOCIETY: SORBY RESEARCH FELLOW.—The committee, representing the Royal Society and the University of Sheffield, appointed to administer the Sorby Research Fellowship Fund, will proceed to the election of a Fellow after Easter. The object of the Fellowship is not to train men for original research, but to obtain advances in natural knowledge by enabling men of proved ability to devote themselves to research. The appointment will be for five years, subject to regulations, a copy of which may be obtained on application to the Royal Society. The emoluments of the Fellow will be approximately £500 per annum. The Fellow elected will be expected to pursue his investigations at the University of Sheffield unless the nature of the investigation requires that the work should be done elsewhere; he will be expected to enter upon his duties as soon after election as possible. Applications from candidates for the Fellowship will be received by the secretaries of the Royal Society, at Burlington House, London, W., up to April 20th. Each application should contain a brief statement of the scientific career of the candidate, including his previous work, and a statement, as precise as possible, of the nature of the work to which he proposes to devote himself if elected. Each candidate is requested to send one reference, but testimonials are not desired.

[1] THE LANCET, Nov. 22nd, 1913, p. 1510.

THE STATE AND THE NATIONAL HEALTH.—We are asked to announce that a public meeting is being arranged by the State Medical Service Association at the Essex Hall, Essex-street, Strand, on or about March 25th to discuss the responsibility of the State for the national health

DR. W. T. GRENFELL, C.M.G., AND LABRADOR — Dr. Grenfell, who has done such good work among the fishermen and people of Labrador, is now in England, and will deliver a series of lectures with the object of raising money for his work. The first lecture, illustrated with lantern slides and kinematograph films, entitled "My Life in Labrador," will be given at Queen's Hall on Monday next, Feb 23rd, when His Excellency the American Ambassador will preside

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

PARLIAMENT was opened by the King in person on Tuesday, Feb 10th.

Chairmanship of Insurance Joint Commission.

Mr. MASTERMAN, who has been Secretary to the Treasury, has entered the Cabinet as Chancellor of the Duchy of Lancaster. He has discharged the duties of chairman of the National Health Insurance Joint Commission and of the Minister specially charged in the House of Commons with the responsibility for the details of the administration of the National Insurance Act. On matters of larger policy the Chancellor of the Exchequer and the Prime Minister gave expression to the views of the Government, but it has been on Mr. MASTERMAN that the burden devolved of answering the almost daily batch of questions arising out of the working of the Act. In consequence of this experience, his knowledge of the complicated provisions of the statute and the regulations under it has become extremely wide For this reason the Prime Minister has decided that whilst Mr. MASTERMAN should receive promotion to Cabinet rank he should retain his [illegible]

The New President of the Local Government Board.

One of the most interesting changes in the Cabinet is the transfer of Mr. JOHN BURNS to be President of the Board of Trade and the appointment of Mr HERBERT SAMUEL as President of the Local Government Board in his place Mr. BURNS has been in charge of the Local Government Board since the present Government accepted office eight years ago He devoted a great deal of his attention and energies there to the administrative side of the department's work, but he also has piloted several important measures through the House of Commons, notably the Housing and Town Planning Act. Mr HERBERT SAMUEL comes to the Local Government Board from the Post Office, but before he became Postmaster General he was Under Secretary at the Home Office. In the latter capacity he won great praise for the manner in which he took charge of the Children Act during its passage through the House of Commons

Assistants to Pharmacists (Qualification) Bill.

Mr. GLYN-JONES has introduced a Bill in the House of Commons "to pr [illegible] of persons entitl [illegible] compounding of [illegible] practitioners" [illegible]

Insured Persons in the United Kingdom.

[illegible] of insured persons in the [illegible] the scope of the National [illegible] 4,077,100 women.

Defective and Epileptic Children.

Mr. J. PEASE, the President of [illegible] introduced in the House of Com [illegible] law relating to the education [illegible] children in England and Wales." It was read a first time.

HOUSE OF COMMONS.

THURSDAY, FEB. 12TH.

Deposit Contributors under the Insurance Act.

Mr. GODFREY LOCKER LAMPSON asked the Secretary to the Treasury what proportion of insured persons were now depo [illegible] and [illegible] avai [illegible] appr [illegible] any honourable Members who are interested.

Insured Persons and Non-Panel Practitioners.

Mr. PETO asked the Secretary to the Treasury what was the amount of the fund on Jan. 1st, 1914, derived from insured persons who had chosen other medical men than those on the panels —Mr. WEDGWOOD BENN said in reply: If the honourable Member's inquiry relates to insured persons who have continued to be attended by non panel medical men as private patients without reference to the provisions of the National Insurance Acts, no information is available as to their number and no separate account is or can be kept in respect of them

Sanatorium Benefit in Kent.

Mr. FRED HALL (Dulwich) asked the Secretary to the Treasury whether his attention had been called to the terms of a circular issued by the Kent Insurance Committee to insured persons to the effect that, owing to the number of patients receiving sanatorium benefit and to the fact that the sum of money available for the purpose was limited, it had become necessary to reduce the quantity of nourishment supplied, whether in the case of a certain contributor the committee had communicated with the tradesman who was under instructions to supply [illegible] ordered for him by the doctor [illegible] and whether arrangements [illegible] tuberculosis patients receiv [illegible] ment ordered for them by their medical advisers — Mr. WEDGWOOD BENN answered My right honourable friend is informed that no general circular has been issued by the Kent Insurance Committee making any such announcement as that suggested in the honourable Member's question. He understands, however, in the case of individual insured persons who have already been in receipt of the special nourishment for the full period for which such grants of nourishment are ordinarily given, the committee, while continu [illegible] have in some cases [illegible] further grant of special [illegible] immediate claims of ot [illegible] of securing the employm [illegible] the greatest advantage [illegible] of the insured person [illegible] refers, and a letter was a [illegible] medical adviser notifying him of their decision in the matter. He has, however, continued to receive domiciliary treatment under the supervision of the medical adviser, who recommended in his case the provision of a shelter for open-air treatment, with which he has been supplied. A further grant of special nourishment was in due course considered and allowed, and orders for its supply were issued on Monday, Feb. 9th.

Tuberculosis Benefit.

Mr. SOAMES asked the Secretary to the Treasury how many persons had received treatment for tuberculosis under [illegible] n sana [illegible] NN said [illegible] d for is [illegible] ment at an early date

Bovine Tuberculosis.

Mr. CHARLES BATHURST asked the President of the Board [illegible] proposed to take any and, if any, what steps to encourage stockowners to report to the local authorities cases of bovine tuberculosis existing on their holdings.—Mr. RUNCIMAN wrote in reply: Up to the present £1686 7*s.* 1*d.* has been paid by the Board of Agriculture towards the cost of compensation under the Tuberculosis Order of 1913, but there is a large number of accounts not yet received from the local authorities, some dating from the September quarter. The Board are in communication with the Treasury in regard to a revision of the basis of valuation and the scale of compensation prescribed in the Order.

Registration of Nurses.

Dr. CHAPPLE asked the Secretary of State for the Home Department whether his attention had been called to instances of the abuse of nurses' uniforms during the past few months; and whether he would give his support to a Bill for the State registration of nurses in order to meet this and other evils that were leading to the scarcity of nurses in the ranks of the profession.—Mr. MCKENNA replied: During the past few months my attention has not been called to any case of the kind. The police will make inquiry, but so far as they are aware such cases are of very rare occurrence. Recent Bills on the subject of the registration of nurses have not touched on this matter, and there would be serious difficulties in framing any provision of the nature suggested. I cannot make any promise with regard to a Bill.

MONDAY, FEB. 16TH.

Departmental Committee on Excessive Sickness.

Mr. WEDGWOOD BENN (on behalf of the Chancellor for the Duchy of Lancaster) informed Mr. G. LOCKER-LAMPSON that the Departmental Committee on Excessive Sickness under the National Insurance Act was still taking evidence, and his right honourable friend had no knowledge when it would complete its labours.

Milk and Dairies Bill.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether it was proposed to reintroduce the Milk and Dairies Bill this session.—Mr. HERBERT SAMUEL wrote in reply: The matter is engaging my close attention, but I am not yet in a position to make any statement with respect to it.

TUESDAY, FEB. 17TH.

Medical Benefit.

Mr. SNOWDEN asked the Secretary to the Treasury to state, with regard to England, Scotland, and Wales respectively, for the latest dates for which he had the figures, how many doctors were on the panel, how many chemists had contracted to supply medicine, and what was the average cost of drugs and appliances per insured person.—Mr. WEDGWOOD BENN replied: The approximate numbers of medical men on panels in England, Scotland, and Wales respectively are 16,300, 2700, and 1250 respectively, including medical men who are on more than one panel. The numbers of individual chemists who have contracted to supply medicine cannot be given without calling for a special return from all the Insurance Committees in Great Britain. The information asked for in the third part of the question will not be available until a final settlement of accounts has been effected by all Insurance Committees with the chemists on their panels for the past year.

Hospital Accommodation for Metropolitan Police.

Mr. TOUCHE asked the Secretary of State for the Home Department whether his attention had been called to the lack of a hospital or nursing home for members of the Metropolitan Police Force suffering from ordinary ailments where they could receive proper treatment and attention for which no suitable provision was made at police stations or section houses at present; and was the question of better provision when on the sick list under consideration.—Mr. MCKENNA answered: A central police hospital or nursing home for the Metropolitan Police would not be as satisfactory as the existing arrangement, under which members of the force who need hospital treatment are admitted to a hospital near to their homes, where they can be visited conveniently and without much expense by their families and friends. When the illness does not require hospital treatment, the men are attended at their own homes by the divisional surgeons. Suitable sick rooms are provided for single men at police stations and section houses, where they are treated by the divisional surgeons unless hospital treatment is necessary. The single men form only one-fourth, and the proportion of sickness among them is very small.

WEDNESDAY, FEB. 18TH.

Panel Chemists.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury whether he was aware that panel chemists in several districts, particularly in Manchester, Salford, and Scotland, were dissatisfied with their position and prospects of full payment of their accounts under the National Insurance Act; and if so, what the Government proposed to do to avoid the danger of insufficiency or inferiority of medicines supplied to the public.—Mr. WEDGWOOD BENN (who replied) said: My right honourable friend is not aware of any such general dissatisfaction in Scotland. The chemists on the panel in Manchester and Salford expressed dissatisfaction at the arrangements in force in those areas during 1913, but it is understood that they have renewed their agreements for the current year und[illegible] [illegible]]eir protection against extravag[illegible] [illegible] he second part of the question t[illegible] [illegible] which doctors and chemists have entered into provide ample safeguards both as regards the quality and the sufficiency of the supply of medicines.

BOOKS, ETC., RECEIVED.

Scarborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with board, residence, &c. Also Junior House Surgeon. Salary £80 per annum, with board, residence, &c.

Sheffield, East-End Branch of the Children's Hospital (Out-patient Department).—Female House Surgeon. Salary £75 per annum, with board and residence.

Sheffield Royal Infirmary.—House Surgeon, unmarried. Salary £80 per annum, with board and residence.

Sheffield Union Hospital, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, rations, &c.

Singapore Infectious Diseases Hospital.—Medical Superintendent. Salary 4200 dollars for the first, 4500 dollars for the second, and 4800 dollars for the third year, with furnished quarters.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

Stockport Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence.

Sunderland Royal Infirmary.—House Physician. Salary £120 per annum, with board, residence, and laundry.

Swansea General and Eye Hospital.—House Surgeon. Salary £125 per annum, with board, washing, and attendance.

West Bromwich County Borough Education Committee.—Female School Medical Officer. Salary £250 per annum.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Clinical Assistants to Out-patients.

Western General Dispensary, Marylebone-road, N.W.—Honorary Physician. Also Honorary Radiographer.

West Ham and Eastern General Hospital, Stratford.—Junior House Physician. Salary at rate of £75 per annum, with board, residence, and washing.

West London Hospital, Hammersmith-road, W.—Two House Physicians, Three House Surgeons, and Resident Casualty Officer for six months. Board, lodging, and laundry allowance provided.

West Riding County Council Education Committee.—Eye Specialist. Salary £350 per annum.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with board, apartments, and washing.

Wolverhampton and Staffordshire General Hospital.—Resident Medical Officer. Salary at rate of £125 per annum, with board, rooms, and laundry.

Woolwich Infirmary, Plumstead.—Assistant Resident Medical Officer, unmarried. Salary £180 per annum, with apartments, rations, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Crediton, in the county of Devon; at Knaresborough, in the county of Yorks; and at Ongar, in the county of Essex.

Births, Marriages, and Deaths.

BIRTHS.

Donald.—On Feb. 12th, at Liskeard, Cornwall, the wife of John Donald, M.D., of a daughter.

Pringle.—On Feb. 11th, at Withington-road, Whalley Range, to Dr. and Mrs. John Pringle, a son.

MARRIAGES.

Frankau—McDougall.—On Feb. 11th, at All Saints' Parish Church, Milford-on-Sea, Claude Frankau, F.R.C.S., to Edith Lorne, third daughter of the late A. F. McDougall, of Rendham, and Mrs. McDougall.

Frost—Rawlins.—On Jan. 15th, at St. Luke's Church, Jullundur, India, Lieutenant-Colonel G. H. Frost, I.M.S., to Sara, daughter of the late Major-General J. S. Rawlins.

DEATHS.

Gilchrist.—On Feb. 8th, at Cimiez, Nice, Dr. A. W. Gilchrist, aged 58 years.

Maxwell.—On Feb. 13th, at 29, Woolwich Common, Woolwich, Theodore Maxwell, M.D., B.A., B.Sc., aged 66.

Paul.—On Feb. 14th, at "Costebella," Torquay, John Ernest Paul, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HIGHER EDUCATION OF WORKING PEOPLE.

The report of the University of London Joint Committee for the Promotion of the Higher Education of Working People on the work of the four years 1909-13 has been issued, and forms an interesting document. This committee, which was established by the University in 1909 as a result of representations made to the University by the Workers' Educational Association to promote the extension of university teaching among working people, is constituted of seven representatives each from the University Extension Board and the Workers' Educational Association, the University representatives guarding the standard of the teaching while the Association's representatives guide its direction into channels suited to the requirements of those who are to benefit from its operations. Within certain limits the students are left free to choose their subjects and to have a voice in the choice of their tutor and in the conduct of the class meetings. On the other hand, each student has to sign an undertaking to attend regularly throughout the three years' course and to write a satisfactory number of papers for the tutor on questions connected with the subject of study. Each class meets once a week for 24 weeks in the session, the time allotted being two hours, of which the first hour is devoted to the lecture, the second being given up to free discussion and consideration of individual difficulties. The subjects of study comprise history, literature, economics, sociology, political science, and biology, controversial questions, which inevitably occur in these subjects, being treated with strict impartiality. The progress of the movement may be estimated from the fact that starting in two classes established in 1907 by the University of Oxford to-day every university and university college in England and Wales is responsible for one or more classes. If one had any doubt of the possibilities for good of such a movement it would surely be dispelled on reading the expressions of opinion, quoted in the report from some of the students: they are broad, penetrating, discriminating in idea, and lucidly worded. It seems regrettable that so admirable an institution should be cramped in its energies for lack of funds. The beneficent character of a movement which automatically selects the fittest for improvement should secure for it the public support it needs.

HEALTH AND HOSPITALS IN TRINIDAD.

A report, prepared by Mr. S. W. Knaggs, C.M.G., Colonia Secretary, on the Blue-book of Trinidad and Tobago for the year 1912-13, has been presented to Parliament. It gives the estimated population of Trinidad as 312,790 and that of Tobago as 20,762. The infirm population included 811 deaf and dumb persons, 533 blind, 952 mentally deranged, and 349 lepers. The births during the year numbered 11,711 and the deaths 10,295. The general health was good. There were six cases of bubonic plague, but the energetic precautions of the Sanitary Department prevented any spread of the disease. A serious outbreak of dysentery, lasting from June to December, 1912, occurred in Tobago; there were 3179 cases and 466 deaths. The outbreak was attributable to a defective water-supply and to the want of proper sanitary supervision, and measures are being taken to deal with the recommendations of the medical authorities under these heads. A very important and successful conference assembled in 1913 to consider the desirability of adopting general measures for the prevention and treatment of tuberculosis, an increasingly prevalent disease in the West Indian Colonies. Proposals for giving effect to the measures advocated at this conference are now under the consideration of the Trinidad Legislature.

The Colonial Hospital, Port of Spain, with 320 beds, is the most important in the colony. The number of patients admitted during the year was 6451, the number discharged 5668, and the daily average in hospital 291. The number of deaths was 823. Of those discharged, 2004 were cured, 3453 were relieved, and 211 were not improved. At the San Fernando Hospital, which has 120 beds, 3004 persons were admitted and 2569 discharged, the daily average in hospital being 102. District hospitals are also maintained by the Government at Tobago, Arima, St. Joseph, Tacarigua, Couva, Princestown, and Cedros, with an aggregate accommodation of 246 beds. The number of patients in these on March 31st, 1913, was 182. In addition, there are small temporary hospitals at Chaguanas, Sangre Grande, and Mayaro. There are two hospitals devoted entirely to the treatment of persons suffering from yaws—one in Trinidad and the other in Tobago. The former has accommodation for 200 patients and the latter for 160. The use of salvarsan in the treatment of this disease continues to give very favourable results, the number in the Trinidad Hospital having been reduced during the year from 135 to 32, and those in the Tobago Hospital from 79 to 15. These numbers have, however, again increased, owing to fresh cases having been brought in. The Lunatic Asylum in Port of Spain contained on March 31st, 1913, 672 inmates—408 males and 264 females. There were 64 deaths during the year and the number of discharged was 48, of whom 39 were cured, 6 relieved, and 3 not improved. The average stay of inmates of the asylum was in the case of men 2½ years and in the case of women 4¼ years. The Leper Asylum, situated about two miles west of Port of Spain, contained at the close of the year 283 inmates—202 males and 81 females. The number of admissions was 96, discharges 59, and deaths 39.

MARTIAL AND MEDICINE.

To the Editor of THE LANCET.

SIR,—Turning over Mr. Hugh Platt's "A Last Ramble in the Classics," which you reviewed in THE LANCET of [illegible]

"Lotus nobiscum est, hilaris cœnavit; et idem
[illegible]

Mr. Platt roughly renders the Latin thus:—

"[illegible] our side,
[illegible] y? they cried.
[illegible] died."

This joke Mr. Platt thinks may have been suggested by a Greek epigram by one Lucilius, a pensioner of Nero (Anth., Pal. xi., 257):—

'Ερμογένη τὸν ἰατρὸν ἰδὼν Διόφαντος ἐν ὕπνοις
Οὐκέτ' ἀνηγέρθη, και περίαμμα φέρων.

[illegible]

I am, Sir, yours faithfully,

Feb. 18th, 1914. EDWIN A. EADE.

A MEDICAL MISSION IN PERSIA.

Mr. T. G. Grahame, British Consul-General for the Province [illegible] erected for the purpose in the Shamsabad q[illegible] They comprise a m[illegible] 110 patients, and a [illegible] will shortly be ready for use. [illegible] sists of two European doctors, one European nurse, and 14 Persian assistants; the women's hospital staff consists of two European doctors (ladies). [illegible] A dispens[illegible] of the [illegible] tion with the use of Western drugs. For some years past a leading British firm of chemists has been represented in Ispahan.

METRIC WEIGHTS AND MEASURES.

To the Editor of THE LANCET.

[illegible] to the members of the Bradford Textile Society and the ensuing discussion. This can be obtained from the secretary of the association, Finsbury-court, Finsbury-pavement, London, price 3*d*., and is interesting to others besides the [illegible] by bringing home to them the [illegible] weights and measures connected [illegible] matches in similar couples at right angles. The square decimetre is one of the six sides of a cube which measures 1 litre, and the litre of water weighs 1 kilogramme. Again, five matches placed end to end measure 25 centimetres or ¼ metre. A match and a half on the end of a yard stick will turn it into a metre. The whole eight matches arranged parallel quite close together with the heads alternately up and down measure 2 centimetres in breadth. The weight of the eight matches is 1 gramme. Moreover, six of the [illegible] really consists of. I am, Sir, yours faithfully,

London, Feb. 14th, 1914. W.

MESSRS. A. WULFING AND CO., of Chenies-street, London, W.C., inform us that the King of Spain has granted to them his royal warrant for sanatogen, albulactin, and their other products. Messrs. Wulfing add that albulactin is used in the Royal nurseries for their Majesties' infants.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced. *In 1914.*—

April 13th and 14th (Berlin).—Thirteenth Congress of the German [illegible]

[illegible] the International [illegible] Depage, Bruxelles.)

" [illegible] of the German Surgical Society.

" 19th–21st (Berlin).—"Jubilee" Congress of the German Röntgen Society.

" [illegible]

" [illegible]

May [illegible]

June [illegible]

July [illegible]

" [illegible]

SOCIETIES.

OYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Lord Rayleigh, O.M.: On the Diffraction of Light by Spheres of Small Relative Index.—Prof. H. E. Armstrong and Prof. F. P. Worley: (1) Studies of the Properties Operative in Solutions. XXXI., Sulphonic Acids and Sulphuric Acid as Hydrolytic Agents: a Discussion of the Constitution of Sulphuric and Other Polybasic Acids and of the Nature of Acids; (2) XXXII., The Influence of Sulphonates on the Hydrolytic Activity of Sulphonic Acids: a Contribution to the Discussion on the Influence of Neutral Salts.—Prof. H. E. Armstrong, Mr. R. T. Colgate, and Mr. E. H. Rodd: Morphological Studies of Benzene Derivatives. V., The Correlation of Crystalline Form with Molecular Structure: a Verification of the Barlow-Pope Conception of "Valency-Volume."—Prof E. Wilson: The Magnetic Properties of Iron when Shielded from the Earth's Magnetism (communicated by Prof. J. A. Fleming).—Dr. J. N. Pring: The Occurrence of Ozone in the Upper Atmosphere (communicated by Sir E. Rutherford).—Mr. W. A. D. Rudge: (1) On a Meteoric Iron from Winburg, Orange Free State (communicated by Prof. B. Hopkinson); (2) On the Electrification Produced during the Raising of a Cloud of Dust (communicated by Sir J. J. Thomson).—Prof. W. M. Thornton: The Electrical Ignition of Gaseous Mixtures (communicated by Sir Charles Parsons).

OYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SECTION OF ODONTOLOGY (Hon. Secretaries—Robert McKay, F. Coleman): at 8 P.M.

Mr. F. St. J. Steadman: Oral Sepsis as a Predisposing Cause of Cancer.

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—H. Batty Shaw, John Fawcett): at 5.30 P.M.

Dr. R. Hutchison and Dr. John Parkinson: Case of Paroxysmal Tachycardia in a Child of 2⅔ Years.

Dr. Gordon R. Ward: Secondary or Symptomatic Leukæmia with Special Reference to Cancer with Bone Metastases.

THURSDAY.

SECTION OF NEUROLOGY,
SECTION OF OPHTHALMOLOGY, and } Combined Meeting.
SECTION OF OTOLOGY: at 8 P.M.

Cases and Demonstration:

Physiological and Pathological Nystagmus of Labyrinthine Origin.

Discussion (at 9 P.M.):

On Nystagmus (to be opened by Mr. Holmes Spicer, Dr. James Taylor, and Mr. Sydney Scott).

The discussion will be continued on Wednesday, March 4th, at 8.30 P.M., when Dr. Llewellyn, Dr. Dan McKenzie, and others will take part in it.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—F. Langmead, Philip Turner, William J. Midelton): at 4.30 P.M.

Dr. F. G. Crookshank: Incurvate Little Fingers in an Afro-Aryan Child.

Dr. J. F. O'Malley: Extensive Cicatricial Pharyngeal Diaphragm following Scarlatina.

Mr. W. Girling Ball: Cyst of the Cæcum.

Mr. W. Barrington Ward: Enlargement of the Mammary Gland in a Boy.

Dr. Edmund Cautley: (1) Multiple Subcutaneous Tumours in the Arm; (2) Subacute Nephritis, with Ascites and Uræmia, ending in Recovery; (3) Serous Apoplexy (?).

Dr. Langmead: So-called Congenital Hypertrophic Stenosis of the Pylorus.

And other Cases.

SECTION OF EPIDEMIOLOGY (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Lecture:

Sir Ronald Ross, K.C.B., F.R.S.: Malaria in Cyprus and Greece.

IEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical and Pathological Evening.

RITISH OTO-LARYNGOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

WEDNESDAY.—4 P.M., Exhibition of Cases.

IUNTERIAN SOCIETY, Guy's Hospital, London Bridge, S.E.

WEDNESDAY.—4 P.M., Clinical Afternoon. Dr. Iredell: Demonstration of Diathermy and the Results of the Treatment in Certain Cases.—Mr. J. G. Saner: Cases of Ileo-sigmoidostomy and Colectomy Operated on between January and June, 1910 (with Sir Arbuthnot Lane's kind permission).—Dr. Hunt: Demonstration of the Electro-cardiograph.

ECTURES, ADDRESSES, DEMONSTRATIONS, &c.

OYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Milroy Lecture:—Dr. F. Shufflebotham: The Hygienic Aspect of the Coal Mining Industry in the United Kingdom. (Lectures II. and III.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Hunterian Lectures:—Prof. A. Keith: Evolution and Diseases of the Anthropoid Apes: Lecture IV., Injuries and Diseases of Anthropoid Apes; Lecture V., Structural Changes Due to Age, Sex, and other Conditions; Lecture VI., A Résumé of the Present State of [illegible] Various Forms of Extinct Anthropoids. [illegible] from the Museum of the College; the [illegible] sed.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 P.M., Lecture:—Mr. J. L. Mummery: Common Errors in Diagnosis—Rectal.

TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Lecture:—Mr. K. Campbell: Common Errors in Diagnosis—Eye.

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. L. Guthrie: Common Errors in Diagnosis—Children.

THURSDAY.—4 P.M., Mr. A. Carless: Clinique (Surgical). 5.15 P.M., Lecture:—Sir StClair Thomson: Common Errors in Diagnosis—Nose and Throat.

FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Pritchard: Meningitis.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Meningitis.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: *Diseases of Women.* 5 P.M., Lecture:—Mr. Addison: *Diseases of the Breast.*

THURSDAY.—9 A.M., Dr [illegible] Bacterial Therapy Department. 10.30 A.M., Dr. [illegible] Demonstration. 12 noon, Lecture:—[illegible] rological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Addison: Diseases of the Breast.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. Addison: Diseases of the Breast.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, *Prince of* Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Medical In-patients (Dr. R. M. Leslie). [illegible]

TUESDAY.—2.30 P.M., Operation [illegible] (Dr. A. G. Auld); Surgical [illegible] (Dr. A. E. Giles). X Rays [illegible] The Bismuth Meal and its [illegible] In-patient (Dr. A. J. Whiting). 4.15 P.M., Mr. Gillies: [illegible] Polypi.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P. [illegible] (Dr. A. E. Giles). [illegible] Clinics:—Medic [illegible] (Mr. Carson); [illegible]

FRIDAY.—2.30 P.M. [illegible] (Dr. A. G. Aul [illegible] Brooks). 3 P.M. [illegible]

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-pat [illegible] —10 A.M. Dr. Singer: Medical. Mr. [illegible] noon, Mr. G. N. Biggs: Throat, Nose, [illegible] Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine.

TUESDAY.—Out-patient Demonstrations:—10 A.M.: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin. ——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

Thursday.—Out-patient [illegible] Medical. Mr. H. Cur[illegible] Throat, Nose, and E[illegible]

[illegible] Medical. Mr. [illegible] Skin.—[illegible] Sir John Rose [illegible] Surgery. [illegible] Medical. Mr. [illegible] Bickerton: [illegible]

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on the Neuroses and Psychoses of Children:—

Monday.—4.15 P.M., Dr. F. Warner. Cultivation of Mental Powers and Systematic Training.

[illegible] Dr. W. J. Hadley: The [illegible] The Skin.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

Wednesday.—4.30 P.M., Demonstration:—Dr. Fenton: Cases of Non-tuberculous Diseases of the Chest.

THE THROAT HOSPITAL, Golden-square, W.

Monday.—5.15 P.M., Special Demonstration of Selected Cases.
Thursday.—5.15 P.M., Clinical Lecture.

[illegible]ENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday.—3 P.M., Lecture:—Dr. A. Wylie: The Causes and Treatment of Hoarseness.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

Tuesday and Friday.—3.30 P.M., Clinical Lecture:—Mr. L. Paton: Optic Atrophy.

QUEEN'S HOSPITAL FOR CHILDREN, Board Room of the Hospital, Hackney-road, N.E.

Thursday.—4 P.M., Lecture:—Mr. S. Stephenson: The Common Eye Disease of Childhood—Phlyctenulosis.

CANCER HOSPITAL, Museum of the Hospital, Brompton, S.W.

Post Graduate Lectures on the Diagnosis and Treatment of Cancer:—

Wednesday.—5 P.M., Mr. Swan: Tumours of the Bladder.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

Tue[illegible]
Thu[illegible]

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Room of the Institute, 37, Russell-square, W.C.

Course of Instruction for Tuberculosis Officers, School Medical Officers Medical Practitioners, &c.—

Friday.—5 P.M., The Diagnosis and Treatment of Tuberculosis, &c.—Lecture VI.—Dr. C. Wall: Treatment—General.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Tuesday.—3 P.M., Prof. W. Bateson: Animals and Plants under Domestication. (Lecture VI.)
Saturday.—3 P.M., Prof. Sir J. J. Thomson, O.M.: Recent Discoveries in Physical Science. (Lecture I.)

MANCHESTER HOSPITALS POST-GRADUATE CLINIC.

Monday.—Manchester Children's Hospital, Gartside-street.—[illegible]

[illegible] Optic Neuritis and Atrophy.

RO[illegible] COURSES, Dublin.

[illegible] Rupture of the Uterus. [illegible] of Patients and Minor Operations.

Tuesday.—10 A.M., Major Operations.
Wednesday.—10 A.M., Obstetrical Lecture: The Varieties of Contracted Pelvis. 11 A.M., Examination of Patients and Minor Operations.
Thursday.—10 A.M., Major Operations.
Friday.—10 A.M., Gynæcological Lecture: The Operative Treatment of Backward Displacement of the Uterus. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1913 were given in THE LANCET of Dec. 27th, 1913.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1913 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.	
One Year	£1 1 0
Six Months	0 12 6
Three Months	0 6 6

TO THE COLONIES AND ABROAD.	
One Year	£1 5 0
Six Months	0 14 0
Three Months	0 7 0

(The rate for the United Kingdom will apply also to [illegible] India whose rates of pay, including [illegible]) per month.)

[illegible] commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. W L. Allott, Blacker; Ardath Tobacco Co., Lond.; Australian Book Co., Lond.; A. G. L.; Ariel and General Repairs, Lond., Managing Director of; After-care Association, Lond.; Association for Promoting the Training and Supply of Midwives, Lond., Secretary of; Association of Public Vaccinators of England and Wales, Lond., President and Council of; Messrs. E. M. Ashley, Southport; Mr. E. Arnold, Lond.; Addenbrooke's Hospital, Cambridge, Secretary of; Anglo-American Pharmaceutical Co., Croydon.

B.—Mr. W. Bryce, Edinburgh; Mr. E. R. Berwick, Hemel Hempstead; Messrs. Burge, Warren, and Ridgley, Lond.; Messrs. Butterworth and Co., Lond.; Bedford County Hospital, Secretary of; British Guiana Society for the Prevention and Treatment of Tuberculosis, Georgetown; Dr. J. H. Bartlett, Chichester; Dr. E. A. Bullmore, Wisbech; Mrs. Cloudesley Brereton, Lond.; Mr. H. M. Barlow, Lond.; Messrs. Burroughs, Wellcome and Co., Lond.; Colonel T. H. Browne, I.M.S., Mentone; Messrs. W. H. Bailey and Son, Lond.; *Barry Dock News*, Manager of; Messrs. C. Barker and Sons, Lond.; Birmingham Maternity Hospital, Hon. Secretary of; *Blackburn Times*, Manager of; Brentwood Asylum, Medical Superintendent of; Birmingham Corporation, Clerk to the; Messrs. Boulton and Paul, Norwich; Messrs. R. and J. Beck, Lond.

C.—Colman's Advertising Offices, Lond.; C. C. S., Newcastle, Staffs; Mr. J. Jackson Clarke, Lond.; Mr. H. Y. Collis, Stourbridge; Dr. Myer Coplans, Leeds; Messrs. Corbyn, Stacey, and Co., Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Cumberland Infirmary, Carlisle, Secretary of; *Chester Courant*, Manager of; Mr. F. Collis, Stourbridge.

D.—Dorland Agency, Lond.; Dr. Dreyer, Florence; Dewsbury and District General Infirmary, Secretary of; Decimal Association, Lond.; Dr. Binnie Dunlop, Lond.; Davis Gas Stove Co., Lond.; Messrs. W. Dawson and Sons, Lond.; Dr. C. Damoglou, Cairo; Messrs. S. Deacon and Co., Lond.; Derby County Asylum, Mickleover, Medical Superintendent of; D. M. M.; Denver Chemical Manufacturing Co., Lond.; Mr. W. A. Dawson, Preston; Dr. Dunstan, Paignton.

E.—Epsom College, Lond., Secretary of; Eugenics Education Society, Lond., Hon. Secretary of; Dr. John Eyre, Lond.; Sir Frederic Eve, Lond.; Evian-Cachat, Lond., Manager of.

F.—Mr. C. C. J. Frost, Lond.; Messrs. Fannin and Co., Dublin; Dr. H. Fraser, Kuala Lumpur; Mr. Temple Fischer, Berkhamsted; Mr. W. B. Forster-Bovill, Lond.; Dr. E. T. Fraser, Glasgow Messrs. Ferris and Co., Bristol; Dr. G. Flumerfeldt, Victoria, B.C.; Messrs. Fieldhall, Lond.

G.—Mr. J. H. P. Graham, Wallasey; Dr. W. Gilfillan, Port of Spain; General Infirmary, Leeds, Secretary of; Glasgow Maternity and Women's Hospital, Secretary of; Dr. Major Greenwood, Lond.; Mr. D. G. Griffiths, Aberystwyth; Mr. E. G. Gauntlett, Lond.; Miss J. M. Graham, Edinburgh; General Lying-in Hospital, Lond.

H.—Dr. C. O. Hawthorne, Lond.; Messrs. J. Heywood, Manchester; Messrs. C. J. Hewlett and Son, Lond.; Mr. Basil Hughes, Bradford; Holborn Surgical Instrument Co., Lond.; Dr. P. Hamill, Lond.; Mr. Charles Higgins, Lond.; Mr. J. Hicks, Lond.; Mr. E. Martin Harvey, Lond.; Hercules Tyre and Equipment Co., Northampton; Mr. N. Bishop Harman, Lond.; Messrs. Harris and Gillow, Lond.; Miss Hamilton, Lond.

I.—Government of India Department of Education, Delhi, Secretary of.

J.—Mr. H. W. Jackson, Lond.; Dr. D. W. Carmalt Jones, Lond.; Messrs. J. F. Jones and Co., Paris.

K.—Mr. A. P. Kothare, Bombay; Messrs. H. S. King and Co., Lond.; King Edward VII.'s Hospital, Cardiff, Secretary of; Dr. J. R. Keith, Driffield; Dr. R. S. Kolbé, Paris; Mr. F. C. Kessell, Lond.; Messrs. Kutnow and Co., Lond.; Dr. Fritz Koch, Berlin.

L.—Messrs. Longmans, Green, and Co., Lond.; Leicestershire County Council, Leicester, Secretary of; Leeds Public Dispensary, Secretary of; Dr. P. Laver, Colchester; Local Government Board, Lond., Secretary of; Dr. R. Bruce Low, Lond.; Dr. J. Litinski, Mentone; London Hospital Medical College, Secretary of; Mr. E. Leitz, Lond.; Dr. Alexander Lundie, Cathcart; London and Counties Medical Protection Society, Lond., Secretary of; Dr. S. C. Lawrence, Lond.; Mr. K. Lohner, Berlin; Mr. H. K. Lewis, Lond.; Lancashire County Council, Preston, Clerk to the; Liverpool Corporation, Superintendent of; Messrs. Lee and Nightingale, Liverpool; Leicester Education Committee, Secretary of; Mr. H. H. Lacy, Warwick.

M.—Dr. W. A. Milne, Barnsley; Dr. A. L. McMillan, Glasgow; Dr. F. R. Holmes Meyrick, Brighton; Mr. McLewin, Bath; Maltine Manufacturing Co., Lond.; Mr. R. Mosse, Berlin; *Midland Counties Herald*, Birmingham, Manager of; Mr. C. Mansell Moullin, Lond.; Dr. M. M'Intyre, Glasgow; Mr. J. E. May, Lond.; Mr. A. Ernest Maylard, Glasgow; Dr. J. Marnan, Gloucester; Dr. W. Miller, *Rayleigh*; M. O. H., Lond.; Medical Agency, Lond., Secretary of; Manchester Hospital for Consumption, Secretary of; Messrs. F. Mundy, Gilbert and Co., Birmingham.

N.—Nottingham Guardians, Clerk to the; National Health Insurance Commission (England), Secretary to; Captain V. B. Nesfield, I.M.S., Banda; Dr. A. T. Nankivell, St. Austell,

O.—Oxford University Press, Lond.

P.—Dr. Owen Paget, Fremantle; Preston Royal Infirmary, Secretary of; Surgeon A. C. Paterson, R.N., Canton; Portsmouth Town Council, Chief Clerk to; Press Association, Lond.; Poplar Dispensary for the Prevention of Consumption, Lond.; Messrs. G. Pulman and Sons, Lond.; Mr. F. Priestley, Birmingham; Mr. W. H. Parr, Bristol; Messrs. Parke, Davis, and Co., Lond.

Q.—Messrs. Quibell Bros., Newark.

R.—Royal Infirmary, Manchester, Secretary of; Royal Ear Hospital, Lond., Secretary of; Messrs. Reynell and Son, Lond.; Dr. Alexander Ruete, Preston; Mr. J. Grant Ramsey, Lond.; Mr. E. Halford Ross, Lond.; Dr. J. D. Rolleston, Lond.; Dr. Vittorio Ronchetti, Milan; Mr. H. Betham Robinson, Lond.; Royal Maternity Charity of London, Secretary to; Royal Society, Lond., Assistant Secretary of; Dr. R. R. Rentoul, Liverpool; Dr. A. H. S. Roberts, Portsmouth; Mr. R. A. Rotherham, Coventry; Royal Portsmouth Hospital, Secretary of; Rochester and Chatham Printing Co., Manager of; Messrs. Reynolds and Branson, Leeds.

S.—Dr. H. K. Smyth, Lond.; Lieutenant K. I. Singh, I.M.S., Lahore; The "Sanitas" Co., Lond.; Dr. Soutar, Gloucester; Sheffield Corporation, Clerk to the; Mr. A. Shelmerdine, Liverpool; Dr. H. Batty Shaw, Lond.; Messrs. W. B. Saunders Co., Lond.; Dr. J. S. B. Stafford, Manchester; Dr. Seheult, Port of Spain; Dr. Theodore Shennan, Edinburgh; Society for the Advancement of Clinical Study in New York; Dr. Lionel Scargill, Luton; "Scalpel," Lond.; Suburban Newspapers, Ltd., Lond.; Messrs. F. W. Sears, Lond.; Messrs. Sherratt and Hughes, Manchester; Stockport Infirmary, Secretary of; Sunderland Royal Infirmary, Secretary of; State Medical Service Association, Lond., Secretary of; Messrs. G. Street and Co., Lond.; Dr. W. Schwab, Berlin.

T.—Dr. H. E. Symes Thompson, Lond.; Dr. Leslie Thain, Ewyas Harold; Mr. P. Templeton, Brighton.

V.—Dr. H. Walter Verdon, Lond.

W.—Messrs. A. Wulfing and Co., Lond.; Dr. R. J. Willan Newcastle-on-Tyne; West London Hospital, Lond., Secretary of; Warneford, Leamington, and South Warwickshire General Hospital, Secretary of; West Bromwich Education Committee, Director of; Western General Dispensary, Lond., Secretary of; Messrs. J. Wright and Sons, Bristol; Dr. Arthur Whitfield, Lond.; Dr. Leonard Williams, Lond.; Wellcome Chemical Research Laboratories, Lond.; Dr. Beckwith Whitehouse, Birmingham; W. E. C. L.; West Riding County Council, Wakefield; Messrs. F. Williams and Co., Lond.; Wolverhampton and Staffordshire General Hospital, Secretary of; Messrs. Wideumann, Broicher, and Co., Lond.; Mr. A. G. Weaver, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. E. D. Atwell, Hawes; Messrs. Arnold and Sons, Lond.; A. G. L.; A. S. F.

B.—British Drug Houses, Lond.; Messrs. Bresillon and Co. Lond.; Dr. F. D. Blandy, Tynemouth; Messrs. Boyveau and Chevillet, Paris; Bibliothèque de la Faculté de Médecine, Bucarest; Dr. H. Browne, Hoylake; Dr. T. P. Berry, Swindon; Dr. J. A. Bosson, Alford; Mr. W. H. J. Brown, Lond.; Dr. J. Scott Byrne, Bradford; Mr. J. H. Bartlett, Lond.

C.—Mr. C. J. B. Cooke, Crewe; Co-operation of Temperance Male and Female Nurses, Lond., Secretary to; Surgeon H. St. C. Colson, R.N., Lond.; Central London Throat and Ear Hospital, Lond., Secretary of; Cumberland County Council, Carlisle, Secretary of; Miss Scarlett Campbell, Sidmouth; Mr. G. W. Collins, Wanstead; Messrs. Constable and Co., Lond.; C. A. H.; Dr. P. Chapman, Hereford.

D.—Dr. P. Diack, Lond.; Devon County Asylum, Exminster; Messrs. Durant, Radford, and Co., Lond.; Delhi and London Bank, Calcutta; Mr. C. E. Dashwood, Cupar Fife; Dundee Royal Infirmary, Secretary of; Doncaster Royal Infirmary, Hon. Secretary of.

E.—Ernakulam, India, Chief Medical Officer of: E. G. L.; Messrs. Elliott, Son, and Boyton, Lond.; Dr. J. J. English, Lond.

F.—Mr. A. Foerster, Lond.; Mr. H. A. Fenton, Lond.

The Hunterian Lectures

ON

INFANTILISM.

Delivered before the Royal College of Surgeons of England on Feb. 2nd and 4th, 1914,

BY HASTINGS GILFORD, F.R.C.S.ENG.

LECTURE I.

Delivered on Feb. 2nd.

MR. PRESIDENT, LADIES AND GENTLEMEN,—The name "infantilism" was first used by Lasègue, and we are indebted to other French writers, notably Fournier, Hutinel, Meige, Brissaud, and Garnier, for much information and for a valuable classification. Among Italians Taruffi, E. Levi, and Ferranini; among Germans Schaaffhausen and Virchow; among Austrians Arnold Paltauf and Fröhlich; among Americans Cushing and Herter; and among Belgians Hertoghe may also be singled out for their valuable contributions. But of all the works upon this subject the most important is that which has proceeded from the Eugenics Laboratory of the University of London, under the guidance of Professor Karl Pearson. The book on Dwarfism, which has been drawn up by his assistants, Dr. H. Rischbieth and Miss Amy Barrington, with its exhaustive bibliography, its copious *résumé* of cases, its pedigrees and its wealth of pictures, is a rich mine of information for the investigator into the subjects of dwarfism and of infantilism, and I feel bound to put it into the forefront of my lecture not only because of its intrinsic value but because I have drawn upon it for most of my facts. In this book references to more than a hundred cases of infantilism, chiefly ateleiosis, have been gathered together and arranged in historical sequence. Their number not only shows the growing importance of the subject, but also that there is now sufficient material to justify an attempt at a scientific classification.

CLASSIFICATION.

Until recently the best arrangement of the forms of infantilism was that for which we are indebted to the French writers Lorain, Brissaud, and Variot and Pironneau, who have grouped them into types founded upon their more obvious anatomical characteristics. Thus the name of Lorain has become associated with that form of infantilism, usually of lesser degree, in which the bodily proportions are of the adult pattern and in which, according to Brissaud, there is reason to believe that the defect of development is dominated by hypoplasia of the heart and arteries. Brissaud's type was thought to be dependent upon some defect in the action of the thyroid gland, and was therefore termed the myxœdematous type. While Lorain's type is usually characterised by a more thin or angular figure and by debility, in Brissaud's type there is a tendency to fatness. Brissaud's type of infantilism is often of extreme degree—the sex organs are undeveloped and the proportions are infantile. Recently Variot and Pironneau,[1] in describing a case of progeria, suggested the addition of another type which they termed "le nanisme type sénile," in which may be included all cases of dwarfism or infantilism coexisting with emaciation, debility, and other signs indicative of the decrepitude of senile decay.

These types have been of great service and are still useful for descriptive purposes, but they can hardly be retained as the basis of a scientific classification. Though adequate when our knowledge of infantilism was in its infancy, they prove inadequate when we attempt to fit them to our present enlarged conception of this subject. Thus we now know that most of the cases, which were regarded as of the myxœdematous type of Brissaud, are in reality due either to changes in the pituitary gland or are examples of ateleiosis. In Lorain's type again there may be no evidence of anangioplasia, and in Variot's senile type the senility may be nothing but an end result of a prior infantilism.

Not only is there reason to criticise the types into [illegible] meaning [illegible] antilism" [illegible] s usually regarded as synonymous with sex deficiency, as if there could be no infantilism in which the sex organs are normal. But such a conception of infantilism can hardly be entertained. An infant with sexual precocity does not cease to be an infant because its sex organs have ripened, and the adult who is somatically perfect is still a man or a woman despite some lack of development of the reproductive organs. Although the sex organs are infantile the individual as a whole is not necessarily immature except in regard to sex alone.

There is, moreover, great objection to the conception of infantilism as a condition dominated by one set of organs in that the meaning of the word is artificially cramped, seeing that it is necessarily limited in its application to sex-bearing animals or plants. The terms "infantilism" and "infantilate" ought to be as wide in their meaning as "dwarfism" and "dwarfed," and therefore capable of being applied to any animal, not only to the metazoa but to the protozoa, to cells and to organs, as well as to the complex animal, and to plants as well as to animals. This becomes more obvious when we compare the state of infantilism with the state of dwarfism, for we then see how artificial is any definition which limits the meaning of "infantilism" to the sphere of one organ.

The difference between infantilism and dwarfism is that whereas in dwarfism there is a serious delay or arrest of growth, in infantilism there is a similar imperfection of development. The one is purely quantitative, the other qualitative. Dwarfism is, therefore, usually one of the symptoms of general infantilism, but not invariably; for just as a child of 12 may be of adult stature, so also, though but seldom, do we meet with an infantilate who is not a dwarf.

THE ORIGIN OF INFANTILISM.

It is one of the cardinal principles of the doctrine of evolution that every individual, every organ, every cell is liable to depart from established custom and to show diversity of form and function, and such changes or "variations" are themselves liable to vary. Hence, if we put on one side the slighter modifications, we have two degrees of variations, one of which we know as the "continuous variation" or "fluctuation," and the other as the "discontinuous variation" or "mutation." And it is important to realise that though the fluctuation is of lesser degree it need not necessarily be less conspicuous. The real difference between them has been shown by De Vries to lie in the fact of heredity more than in any other circumstance. Now a fluctuation is, as a rule, if not invariably, the outcome of two factors, the one being an inherent tendency to vary and the other a congenial environment or stimulus which calls it forth, or accentuates it when already extant. A mutation, on the other hand, seems to come into being spontaneously without the assistance of any outside help. It is, therefore, in reality the stronger or greater of the two variations; and this, indeed, is shown by the fact of heredity which is its most characteristic feature.

---

[1] Bulletin de la Société de Pédiatrie de Paris, 1910, p. 207. La Clinique Infantile, vol. viii, 1910, p. 705.

Here it may be objected that merely to call anything a variation does not advance our knowledge. But in reality the word carries us a stage nearer to the origin and nature of infantilism, for it enables us to make comparisons with other variations. And, as Professor Bain has shown, the ability to make fresh comparisons or fresh associations of ideas lies at the foundations of a superior intelligence. Moreover, it enables us to adopt a classification which is not dependent upon superficial distinctions, but is fundamental, for by it we are able to find a natural and adequate explanation, not only of the varieties, but of the very occurrence of infantilism.

DEFINITION.—CLASSIFICATION.

We regard infantilism, therefore, as *a conspicuous delay or arrest of development.* The lesser degrees of defective development do not constitute infantilism, seeing that they are not such a departure from the normal as to attract attention or to throw the individual or the part affected out of harmony with the surroundings. But the condition connoted by the word "infantilism" as by the word "dwarfism" is necessarily abnormal or pathological. If we confine our consideration of infantilism to the human being we shall have to recognise two kinds or classes. In the one the man is affected phylogenetically, constituting racial, ethnic, or evolutionary infantilism; in the other ontogenetically, constituting individual or developmental infantilism.

I. EVOLUTIONARY OR PHYLOGENETIC INFANTILISM.

In this class the man as an individual is normal. He can only be regarded as abnormal when considered as the constituent of a people or race as compared with other races of mankind. Just as in some parts of the world nations or peoples have fallen into a state of racial degeneration, so in other cases races may never have arrived at maturity, but still exist in a state of defective development or of actual infantilism. For example, the Japanese, some Chinese, and the Siamese in Asia and the Bantus in Africa show evidences of being racially imperfect when compared with Caucasians. In other nations the evolutionary defect is much more pronounced, constituting a racial abnormality or infantilism. This is the case, for example, with the forest dwarfs of Central Africa, the Bushmen of South Africa, and the Sakai of Malaya. Their evolutionary status shows that they are anthropologically discordant, so that, like an inferior species of animal, they are driven into the forests and deserts, mountains, or other less hospitable parts of the earth's surface.

II. DEVELOPMENTAL OR ONTOGENETIC INFANTILISM.

Just as each of the structural units of the body is liable to degenerate prematurely so also may it continue immature, and it must sometimes happen that this immaturity is of extreme degree, constituting infantilism. Hence it follows that not only is there a degeneration or a dwarfism but also an infantilism of cells, an infantilism of organs, and an infantilism of the individual as a whole. For the sake of completeness each of these varieties of infantilism must be touched upon, although the greater part of our lecture must be devoted to the infantilism of man as a whole.

A. *Infantilism of Cells.*

In all parts of the body single cells or groups of cells are liable to stagnate or even to be arrested in their development. It has been shown that this is particularly likely to happen in those areas in which one kind of tissue terminates abruptly in another kind of tissue or where tracts of some fœtal structure have differentiated into more than one organ at a comparatively late period of development. Thus, at the margin skin and mucous membrane, the lips, the anus, or again in the organs formed out of the primitive segmental organs, islands of ill-developed cells are apt to be displaced and to remain isolated from their normal surroundings. Similarly with the long bones, in which groups of cartilage cells or half-formed bone cells are often left behind by the advancing tide of ossification. Such infantilate cells pent up in uncongenial surroundings, unable to develop, are apt, as Cohnheim has shown, to undergo premature degeneration and to proliferate as cancers.

B. *Infantilism of Organs.*

We may speak in a similar manner of organs which have never accomplished their destiny. If the defect of development be of slight degree no harm results, but if, on the other hand, it be extreme the organ is in a state of infantilism, and as such is prone to degenerate prematurely. Thus, a kidney which shows slight developmental imperfections in the form of lobulations of its surface will probably last its allotted span; but if the defect be more extreme, so that it never gets beyond the infantile stage, it is liable to undergo early fibrosis. So also with the infantilate brain, thyroid, testes, ovary, breast. These and other organs if in a state of striking immaturity are prone to end their developmental career prematurely, falling into senile decrepitude before they have attained their prime.

C. *Infantilism of the Individual as a Whole.*

There is reason to believe that infantilism of cells and of organs may be divided into two classes according to whether the arrest of development is the result of definite causes and is a fluctuation or whether it is to all appearances spontaneous. In this latter event it is prone to show the influence of heredity and is a mutation. General infantilism arranges itself naturally into these same two biological classes. As a fact in the first class the infantilism owes its appearance to two circumstances. One of these is a cause or causes, whatever they may be, but these causes are not in themselves sufficient to produce infantilism, seeing that they may be in operation, even in a concentrated form, without producing so much as a slighter defect of development. This is the case, for example, with the disease toxins, which are among the most important exciters of infantilism. That such causes are by themselves ineffective is proved by the fact that, though their distribution is very common and very widespread, infantilism is comparatively rare. What is needed to produce infantilism is the second and still more important factor, which consists in that cryptic tendency to vary which constitutes the basis of all fluctuations Infantilism of this kind is, therefore, the outcome of an intrinsic or inherent tendency to developmental inhibition assisted by an environment suitable for its production This form of variation is *symptomatic*, seeing that it is the expression of the action of a morbid agent or agents and is of a decadent or regressive type, not making for the improvement of development, but for its deterioration Consequently the causes of this infantilism must invariably be of a deteriorating or damaging kind, such as the disease toxins, deficiency of food, hardship, overwork, or degeneration affecting some special locality of the body As befits a fluctuation it is usually of minor degree, of gradual rather than of abrupt onset

In the second class the infantilism is "idiopathic," spontaneous, or essential In this and in other respects its salient features are of the sort which characterises all mutations Not only does it occur independently of cause or environment, but it begins with comparative suddenness, is, as a rule, of pronounced degree and often hereditary This last feature is by itself sufficient to stamp its nature as a mutation, for it proves that it must be dependent, not upon any contemporary environment, but upon some deep seated remote biological events

CLASS I —SYMPTOMATIC GENERAL INFANTILISM — INFANTILISM AS A FLUCTUATION

The causes of symptomatic infantilism are of two kinds, the one being some poison or other deleterious influence equivalent to a poison introduced from without the other the product of some perversion of one or more of the organs of the body which act upon its development either by means of a secretion or in some more occult manner It is possible that there is a third group due to the withholding of some food or food stimulus essential to the proper development of the body

Symptomatic infantilism may therefore be either (A) toxic, or (B) correlative or possibly (C) deprivational

A TOXIC INFANTILISM

The poisons capable of setting up infantilism are many, the most important being the products of fungi or protozoa living within the body Chief among these are the toxins of syphilis tubercle, malaria, enteric fever, pellagra, scarlet fever, measles, leprosy, and of those organisms responsible for the chronic diarrhœal diseases of infancy Other poisons are introduced from the outside either from saprophytic fungi, as in the case of the yeast plant, or from plants of higher order, such as the poppy or tobacco Lastly, they may be inorganic—as lead mercury, bisulphide of carbon

B CORRELATIVE INFANTILISM

It is recognised that under ordinary conditions there is a strong tendency for standards of growth of one part of the body to harmonise with standards of growth in other parts Each part bears a certain relation to all other parts And this correlation exists not only under normal conditions but is also manifested when conditions are abnormal We have only to witness what happens to the soft tissues when part of a long bone is destroyed, or, still better, when the bone prematurely ceases to grow, to realise that the correlation which exists between the growth of the bone and of the muscle, skin, vessels, and other soft tissues which cover it can readily be adjusted to abnormal conditions In rickets and in achondroplasia, moreover, these adjustments are often very considerable, so that the whole body with its contained organs is occasionally dwarfed in size in order to accommodate it to the abnormal shortening of the bones of the limbs

Adjustments of this sort are not confined to affairs of growth but are also to be witnessed where development is concerned Thus for æons of time it has been the custom for the ripening of the sex organs to coincide with an impulse of skeletal development which rapidly advances the framework of the body to maturity, and this maturation of the skeleton coincides with, or is immediately followed by, corresponding changes in the soft tissues in general It is the fashion now to attribute all these coordinated changes to the influence of a secretion proceeding primarily from the sex glands reinforced by secretions from other endocrine organs But it is possible that we may be a little too hasty in coming to conclusions of this nature, for there is no reason to suppose that bodily correlations are accomplished solely by chemical stimuli emanating from ductless glands Correlations of growth and of development take place in plants, although as yet no one has been able to detect the influence of secretions There is also a period in the evolution of animal forms and in the development of the higher metazoa in which there are important correlations prior to the development of the ductless glands In all these cases the stimulus to correlation appears to be of the nature of a habit or of mnemonics, whereby an act of development in one organ leads to associated acts in other organs Out of this primitive mechanism of correlation the more elaborate machinery of the endocrine organs seems to have been evolved as a more perfect method of accomplishing the same end But it is important to realise that many of the correlations of the body may still to a large extent be prompted by other methods than by the hormones or by inhibitory secretions manufactured in special organs of correlation

Hence in the production of infantilism we sometimes meet with cases which cannot be accounted for by toxic influences, which are apparently not due to the withholding of food or of food stimuli, but seem to be due solely or partly to the influence of correlation In some cases this influence seems to proceed from the derangement or incapacity of an endocrine organ In other cases it is difficult to account for the infantilism on this score The morbid condition apparently arises as the result of correlations of the more primitive type in which the hormones are not concerned

Correlative infantilism may, therefore, be of two kinds (*a*) endocrinous, and (*b*) simple correlative

(*a*) *Endocrinous Infantilism*

There is at present no criterion by which we can decide when any particular infantilism is to be regarded as of endocrinous origin Only one form of infantilism has so far satisfactorily been proved to be due to the absence or defect of an internal secretion, and this is *thyroid infantilism* In this case three requirements are fulfilled 1 Local examination of the gland shows that it is inadequate 2 The administration of the gland or of its extract to a normal person produces symptoms opposed to those which characterise the infantilism 3 The gland or its extract given to the infantilate counteracts the symptoms characteristic of the infantilism Ought we to demand that these three stipulations should be satisfied before we can admit the endocrinous origin of other kinds of infantilism? If so, it can

Lorain than of Brissaud's type, would either not be recorded, or, if recorded, would be confused with symptomatic infantilism. One may venture to suggest that the two cases of infantilism of Lorain type in sisters, published by Ettore Levi,[4] are of this nature. The facts that this infantilism was familial, that there seems to have been no definite cause, that it was of abrupt onset, and the development almost stationary, point to this explanation. At the same time one of the cases was associated with some pituitary enlargement, and this must needs throw some doubt on the exact nature of both of them. They will be referred to again later on.

Ateleiosis of the second class has a striking individuality. Ordinarily ateleiotics of this kind can be recognised at a glance, for they are clearly to be distinguished from achondroplasics, cretins, and other forms of symptomatic infantilism. Their infantile appearance and proportions, as shown in their comparatively big heads, short limbs, small faces, roundness of outline, and in the configuration of their chests and abdomens, serve to distinguish them at once from cases of symptomatic infantilism. An exception must, however, be made in the case of cretins, and possibly of some examples of pituitary infantilism. But the sharp intelligence of the ateleiotic, the clear definition of his physiognomy, distinguish him at once from the stupid, puffy, and ungainly cretin. In achondroplasia the coarseness of type and the conspicuous dachshund deformity are characteristic. Fröhlich's pituitary infantilism is, as a rule, signalised by a peculiar lumpy fatness of the face and trunk and by a florid, purplish hue of the cheeks.

The somatic features of ateleiosis of the first and second classes are so pronounced that when these ateleiotics mix with the public they attract great and embarrassing attention. This is partly their own fault, for they have a way of dressing as miniature men, so that what is incongruous about them is the appearance of childhood with the setting of maturity. Those who adopt the clothes suitable for childhood or infancy, and go about with adults, have no difficulty in escaping unwelcome curiosity. This was well shown in two cases under my observation, in one of which a boy of 14 dressed and posed as a baby without anyone detecting the deception. He for a time played the leading rôle at one of the London theatres, coming on alternately as a baby in arms and as a man about town, and acting both parts with intelligence and distinction. The other, almost until the age of 30, had no difficulty in passing himself off as a child, so that he travelled on the railway with a half ticket without comment. After that age his slightly wizened appearance led to his age being questioned, and he could not longer carry on the deception. Both these cases were examples of asexual ateleiosis. Sexual ateleiotics have more marked physiognomies, more assurance, more mature figures, so that apart from their facial hair they are not so likely to be mistaken for children.

Although ateleiosis is conveniently divided into three classes, it must be recognised that these divisions are artificial, and that, just as it occurs in early fœtal life and is confused with other causes of abortion, so also it may not begin until after puberty and perhaps account for the juvenile appearance of some middle-aged people.

Sporadic Occurrence.

The sporadic appearance of ateleiosis is a noteworthy feature. Common or symptomatic infantilism seems to favour large centres of population where the conditions which give rise to it are rife. Plumbic, alcoholic, malarial, syphilitic infantilism must be more common in those parts in which there is more exposure to lead, alcohol, malaria, or syphilis, and similarly with other forms of symptomatic infantilism. On the other hand, it is possible that ateleiosis, although scattered in its distribution, may be more common in some parts than in others, and the same is true of other sporadic diseases, such as sporadic cretinism and osteomalacia. Possibly it is more common in Italy and France, where the standards of height and of duration of life are a little lower than they are in America, in Great Britain, and in Scandinavia, where stature and development strike a higher average. On the other hand, a large number of ateleiotics met with in variety shows come from Germany or from Austria. Evidently but little can be said upon this topic until ateleiosis is more widely known and reliable figures are forthcoming.

Ateleiosis is Essentially an Infantilism and not a Dwarfism.

Although there can be no doubt that the asexual form is a pure infantilism, the sexual form is sometimes described as "dwarfism," and even as "essential dwarfism." The decision as to what constitutes dwarfism and what infantilism turns upon the nature of growth and of development. If sexual ateleiosis be an affair of growth it is dwarfism; if it be an affair of development it is infantilism. Now, I think it can be satisfactorily shown that it is an arrest of development. This is best accomplished by taking for our example a characteristic and well-known case. And we can hardly do better than select for our type case Charles Stratton, widely known as General Tom Thumb. Although it is true that we have but few details about him, and no accurate measurements of his height, yet we have all that we require for present purposes. In the first place his height, physiognomy, and proportions were conspicuously undeveloped. His nose was of a turned-up or snub pattern, and his face, as shown in some of his earlier portraits, taken when he had reached maturity, was short, his forehead vertically rounded. His body was of childish conformation, not only in respect to its roundness of outlines and to the shape and proportions of thorax and abdomen, but also as to the comparative length of trunk and limbs and of the segments of the limbs. In all these respects he showed stereotyped childhood. Indeed, one may go farther, and say that his formation was immature in respect to his height, for whereas his height was undoubtedly childish his proportions and conformation were infantile. So that whether we regard him from the point of view of his age or of his height his was a case of infantilism. In other words, he was not only conspicuously undergrown but was also underdeveloped. As for his sexual and mental development, they apparently arrived at maturity, for his wife, an ateleiotic of remarkable similarity, gave birth to a child. To make sure of this fact I have got the death certificate of this child, Minnie Warren Stratton. It certifies that she died at Norwich in 1866, at the age of 2 years, from "congestion of the brain," with convulsions.

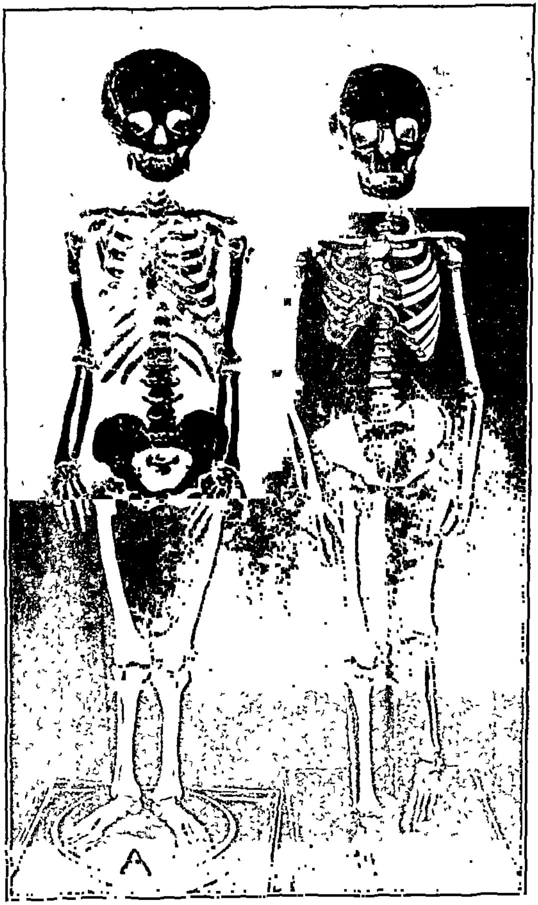
---

[4] Nouvelle Iconographie de la Salpêtrière, tome xxi., 1908, p. 300.

The many important details missing in this outline sketch of Charles Stratton may be filled in from the records of other cases, especially from Rischbieth's description of the Magri family and Ettore Levi's of the Magro family, both of which may be found in the "Treasury of Human Inheritance."

Account of a Specimen in Anatomical Museum of Cambridge University.

I have recently seen a skeleton bearing every evidence of being that of a sexual ateleiotic which serves admirably to demonstrate the infantilate characters. This valuable specimen is in the anatomical museum of the University of Cambridge, and I am greatly indebted to Professor Macalister for permission to examine the skeleton and to have photographs taken. Some of these photographs I now show you. In one it is standing beside the skeleton of a normal child of six. (See figure.)



The ateleiosis skeleton (A) at Cambridge standing beside the skeleton of a child of six.

On the label which goes with the skeleton it is written: "The Skeleton of a Dwarf purchased in Paris and presented by Professor Humphry.—It is the skeleton of a man who had passed the middle period of life. The epiphyses are all ankylosed, the sagittal sutures and the upper part of the lambdoidal are closed, the masseteric, deltoid, and some other muscular ridges are rather pronounced, and there are bony outgrowths from the margins of some of the bodies of the vertebræ. All the upper molar and premolar and two incisor teeth, as well as the lower premolar and two molars, are gone and their alveolar processes have been absorbed. The bones are all well formed and well proportioned one to another."

Professor Sir G. M. Humphry has also published a short description of it elsewhere,[5] in which he says: "The dimensions are as follows: Height, 41 in. (104 cm.); skull, greatest circumference, 19 in. (48·2 cm.): antero-posterior measurements, 6·6 in. (16 cm.); transverse, 5·2 in. (13 cm.); vertical, 4·4 in. (10·8 cm.); spine (skull to sacrum), 13·5 in. (33·7 cm.); clavicle, 3·5 in. (8·5 cm.); scapula, 4·5 in. (11·5 cm.); humerus, 6·9 in. (17·2 cm.); radius, 5·2 in. (12·9 cm.); hand, 4·3 in. (10·5 cm.); pelvis between the iliac spines, 7 in. (17·7 cm.); transverse of brim, 3·2 in. (7·9 cm.); antero-posterior (conjugate), 2·2 in. (5·3 cm.); femur, 10 in. (25·4 cm.); tibia, 8 in. (20·4 cm.); and foot, 5·8 in. (14·4 c.m.)."

In the same article Professor Humphry referred to other dwarfs, including Bébé, Boruwlaski, Charles Stratton, Jeffrey Hudson, and to the pygmy tribes in Africa, and contrasted with these elegant dwarf skeletons "an ill-proportioned and unseemly skeleton from rickets" (osteogenesis imperfecta) which he had also presented to the museum.

In Professor Humphry's first case there is evidence that the arrest of development was greater than the arrest of growth. Thus, when we compare it with the skeleton of a normal child of six, which was just one inch shorter, the dwarf skeleton seems to be the younger in the following particulars. The trunk is longer and the limbs shorter, especially the upper limbs. The thorax is much more conical, like that of an infant. It tapers markedly from the eighth rib upwards, whereas in the child the thorax is of the usual pattern for a child of 6 and much more like to that of the adult. The hands and feet are relatively smaller. One of the most obvious of the signs of immaturity, and which specially serves to stamp the skeleton as ateleiotic, is the marked shortness of the face as compared with the height of the skull; and of still more significance is the presence of a conspicuous depression at the root of the nose. Moreover, the nasal bones, which are short, project in a way which indicates that the nose during life was of the tip-tilted or snub kind. In all these particulars the dwarf skeleton is infantilate. And this is also manifested in the state of the mastoid process and of the mandible, as well as of the upper maxilla. These are of infantile type, the infantilism of the mandible being shown by the depth of the body and by the slope of the ramus. In the frontal region similar immaturity is indicated by the contour of the forehead and by the infantile appearance of the supraorbital region.

---

[5] Brit. Med. Jour., 1891, vol. ii., p. 1157.

This short and very imperfect account of this interesting skeleton will serve to show that it certainly did not come from a race of dwarfs and that there is no known pathological condition except ateleiosis which could account for the appearances found. And this ateleiosis was evidently of the sexual variety, seeing that all the epiphyses are fused, that the muscles during life were evidently of good development, and that apparently the only part which is in advance of the child's skeleton from a morphological point of view is the pelvis. Although there is arrest of growth constituting dwarfism, this is not so pronounced as the arrest of development or infantilism. Evidently the infantilism is the essential feature and at the bottom of the whole series of changes. In some respects this skeleton shows evidences of maturity, although these are superimposed upon those of infantilism. Thus the pelvis, as we have just seen, though still of childish pattern, is more expanded and of more advanced type than that of the child, and this is what we might expect in the skeleton of a sexual ateleiotic. The bones, though elegantly formed, are slightly thicker than those of the child, and their muscular prominences and grooves are decidedly more conspicuous. This is particularly to be noticed in the bones of the arms, forearms, and mandible. In the mandible there is a thin flange of bone projecting prominently from the angle of the otherwise infantile jaw. In the advanced state of its epiphyseal ossification the skeleton is frankly adult.

To sum up the peculiarities of this specimen we may say that in some respects it is like that of a child of about 6 years of age, in others it is infantile, and in yet others it is adult. Of all these features the primary and dominant are those which indicate infantilism. The skeleton is that of a male affected with sexual ateleiosis. The irregularities we have noticed indicate that ateleiosis is more than a mere abnormality. It is associated with disturbances of growth and of development and is therefore a disorder.

Other Skeletons.

So far four dwarf skeletons bearing evidence of pronounced delay of development have been recorded. One was described by Schaafhausen, of Bonn, another by Arnold Paltauf, of Vienna, another is in the museum of the Royal College of Surgeons of Edinburgh, and the fourth is in this museum. In the Vienna and the Edinburgh specimens the sella turcica is moderately enlarged. Schaafhausen does not mention the state of the sella in his case. In the specimen in this museum the sella is normal. In the skeleton of the Cambridge dwarf there also appears to be nothing abnormal about the base of the skull. Although the skull-cap has not been taken off it is possible clearly to see the whole of the base through an aperture in the top of the skull, and also to examine it with the finger passed through the foramen magnum. The part played by the pituitary body in infantilism will be dealt with more fully in my next lecture.

The ateleiotic skeleton in this museum appears to be unique. It is that of Caroline Crachami, in whom the disorder evidently began during fœtal life. It is therefore an example of ateleiosis of the first class. Death took place at the age of 9 years. In addition to this skeleton there is also present in the museum a portrait in oils of the living Caroline Crachami, and in the library is a short account of her written by Sir Everard Home. We have therefore the great advantage of getting important knowledge of the case from three different aspects. These all tend to the conclusion that Caroline Crachami was an example of fœtal asexual ateleiosis. I have myself published a somewhat inadequate description of this case[6] and Professor Keith[7] has elsewhere made some observations upon it in a paper which contrasts the skeleton with that of a case of progeria, also in this museum.

Relations of Sexual and Asexual Ateleiosis.

Of still more importance in serving to stamp sexual ateleiosis as a form of infantilism rather than of dwarfism is the fact that, generally speaking, there is no line of demarcation between sexual and asexual ateleiosis. There are cases which show all gradations between them. In some cases of sexual ateleiosis there is evidence of great delay in the maturation of the sex organs. Thus in the case of Boruwlaski growth did not cease until he had attained the age of 30, and he himself says in regard to his sexual state and perceptions that "at the age of 25 I was like other young lads of 15." He married at 40 and had three children of ordinary stature. Yet two years after his marriage he was still a child in appearance, and this childishness was the occasion of many ludicrous mistakes. For example, the doctor who attended his wife during her first pregnancy could not for a time be made to understand that the little fellow who stood by the bedside was not a child but was Boruwlaski himself and the lady's husband. Boruwlaski's account of himself is very reliable, for he was a gentleman of great intelligence, and of charming simplicity and uprightness of character. His history, size, physiognomy, and proportions all show that he was undoubtedly an example of ateleiosis.

There are yet other cases on record in which ateleiosis was at first of the asexual and afterwards of the sexual variety, the sexual defect having continued until long after the individual had arrived at maturity.

I have myself seen and published a case[8] in which ateleiosis ran through three generations, the father and grandfather being sexually perfect, whereas the grandson at the age of 14 had the sex organs of a new-born child. Ettore Levi[9] has also under the heading of "microsomie essentielle" described a similar case occurring in two generations, in which a father sexually perfect but of conspicuously infantile physiognomy and proportions (sexual ateleiosis) is pictured side by side with his ateleiotic child aged 12½ years with bilateral cryptorchidism It is possible that in course of time these two children will acquire adult sex characters, but whatever may happen in after life their condition as described is that of asexual ateleiosis, for it is not essential to our conception of that disorder that the infantilism of the reproductive organs should persist throughout life In many cases it doubtless does so persist, in others sexual development is seriously delayed, and in others it is normal. But the point I wish now to bring forward is that we must regard all these manifestions of idiopathic sporadic hereditary infantilism as belonging to one group We ought not artificially to separate them into dwarfs and infantilates. The fundamental change is one of development. All are examples of infantilism, whether the evidences of developmental defect be small or great Such evidences are present in greater or lesser degree in all cases, and combine with other characters to form a syndrome which is distinct from that furnished by any other morbid condition

CENTRAL MIDWIVES BOARD—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Feb 19th, Sir Francis H Champneys being in the chair A letter was considered from the Local Government Board transmitting copies of the Order requiring the notification of all cases of ophthalmia neonatorum The Board decided (*a*) that the Local Government Board be thanked for their communication and be asked whether in respect to any future Orders proposed to be issued by them which affect in any way the duties of the Central Midwives Board under the Midwives Act, 1902, or the rules made under the Act, a confidential draft could be laid before the Central Midwives Board for their consideration before it is finally settled, and (*b*) that the chairman be asked to confer with the Local Government Board or their principal medical officer on the Ophthalmia Neonatorum Order just issued A letter was considered from a certified midwife complaining of her suspension by the local supervising authority The Board directed that the county medical officer of health be reminded that no case of suspension not imposed by the proper authority, reported to the Board and recorded in its register, could be upheld by the Board

DONATIONS AND BEQUESTS—The late Mr G C Dobell, of Liverpool, has left £1250 to the Royal Infirmary for the endowment of a bed and £200 each to the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, and the Hospital for Women —The Royal [illegible] val Hospital for Incurables, [illegible] 00 under the will of the [illegible] owing bequests to London [illegible] of the late Mr Charles Ansell have now become payable—namely, £50 000 to King Edward's Hospital Fund for London, £10,000 each to Charing Cross, Middlesex, St George's St Thomas's, Westminster, Guy's St Bartholomew's, and the London Hospitals, an [illegible] King's College H[illegible] al Free Hospital, [illegible] ospital, Brompton Hospital for Consumption and Diseases of the Chest, City of London Hospital for the Diseases of the Chest, Royal Hospital for Diseases of the Chest, London Fever Hospital, London Lock Hospital, Royal London Ophthalmic Hospital, Royal Orthopædic Hospital Queen Charlotte's Lying in Hospital, National Hospital for Diseases of the Heart, Hospital for Diseases of the Throat, Nose, and Ear, Royal Hospital for Sick Children and Women, Great Ormond street Children's Hospital, and Victoria Hospital for Children.

THE MORBID ANATOMY OF TUBERCULOSIS IN MAN[1]

BY THEODORE SHENNAN, M D EDIN, F R C S EDIN,

PATHOLOGIST, ROYAL INFIRMARY, EDINBURGH, UNIVERSITY LECTURER ON MORBID ANATOMY, ETC

THERE must be few in this gathering who have not formed very strong opinions upon the subject of tuberculosis, either from experience at the bedside or as the result of long continued research in the laboratory. To each of us, doubtless, our own opinions possess the great merit of satisfying the canons of common sense and reason But many difficulties are in the way of those who, like myself on this occasion, have to attempt to collate and coördinate these varied opinions, and have to present a reasonable and connected account of even one department of work upon tuberculosis I have come to the conclusion that it is impossible to reconcile these opposing views, and I think that it will be better to discuss them in the light of my own experience, and in doing so shall advance from the general to the more particular.

A. *Statistics dealing with Large Numbers of Individuals*

It will prove useful, to commence with, to inquire what information can be gained by the study of tuberculosis as it attacks large numbers of individuals of both sexes, at all age periods, and in different countries and cities, and to use the results to correct local experiences and data. With this end in view I have investigated the Registrar Generals' returns in England and Scotland, and the results are shown in the following tables.

TABLE I—*Death rates from Tuberculosis in England and Scotland, per Million Living, at 11 Age periods.*

Abstracted and calculated from the Registrar Generals' reports England, 1891–1900, Scotland, 1891–1900, 1901–1910

Age-periods	England 1891 1900			Scotland					
				1891 1900			1901 1910		
	All tubercle	Phthisis	Tubercle not phthisis	All tubercle	Phthisis	Tubercle, not phthisis	All tubercle	Phthisis	Tubercle, not phthisis
All ages	2010	1391	619	2361	1684	677	2090	1380	710
0–5	3930	413	3517	3841	516	3325	3760	403	3357
5–10	724	206	518	1165	376	789	1170	300	870
10–15	669	363	301	1196	745	451	1090	560	530
15–20	1396	1144	252	2435	2124	361	1930	1510	420
20–25	1936	1730	206	2979	2701	253	2430	2100	320
25 35	2302	2135	167	3014	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
35–45	2742	2592	150	2772	2617	155	2310	2100	210
45–55	2492	2362	130	2093	1971	122	1980	1790	190
55–65	2007	1881	126	1632	1573	109	1560	1380	180
65–75	1263	1154	109	1105	1021	84	1090	910	180
75 upwards	612	437	75	542	466	76	502	391	111

The most notable fact brought out by Table I is that in countries so closely related as England and Scotland the conditions of life and apparently the possibilities and modes of infection are so different that the maximum death rate from tuberculosis is reached in England during the 35 to 45 age-period, whereas in Scotland it is reached during the 25 to 35 age-period. The table also shows the predominance of other forms of tuberculosis than phthisis (tabes mesenterica, "scrofula," meningitis, osteitis, and arthritis) in the earlier age-periods, and their progressively diminishing importance as age advances. Further, taking Scotland alone, it will be noticed that while the death-rate from phthisis is steadily falling, being 168 per 100,000 living in the decennium 1891–1900, and 138 per 100,000 living in the decennium 1901–1910, thus continuing the decrease noticed during preceding decennial periods, the death-rate from other forms of tuberculosis, on the contrary, seems actually to be rising at each age-period.

---

[1] Being a report presented at the International Conference on Tuberculosis at Berlin, Oct 23rd, 1913

Table II. shows the differences in the corrected death-rates from tuberculosis in different burghs in Scotland during the first six months of 1913, the statistics available for that period being the first in which the deaths are all referred to the burgh of which the deceased had been an inhabitant.

TABLE II.—*Scotland, January to June, 1913. Corrected Death-rates in certain of the Larger Burghs.*

—	Population to middle of 1913.	Total deaths from all causes.	Deaths from tuberculosis—		
			Total number.	Per 100 of all deaths.	Per 1000 of population living.
All Scotland	4,733,700	39,417	4369	11·08	1·84
Perth	20,200	291	28	9·60	2·77
Greenock	77,800	762	106	13·90	2·72
Inverness	21,300	194	26	13·50	2·44
Glasgow	1,021,500	9,442	1178	12·40	2·30
Paisley	85,600	691	92	13·30	2·15
Coatbridge	43,400	361	45	12·46	2·07
Dundee	165,900	1,522	169	11·10	2·03
Falkirk	35,600	259	33	12·70	1·85
Aberdeen	162,700	1,562	150	9·90	1·84
Edinburgh	320,300	2,474	286	11·56	1·78
Kirkcaldy	40,000	287	34	11·80	1·70
Airdrie	24,000	185	14	7·50	1·16
Forfar	10,400	85	4	4·70	0·77
St. Andrews	15,000	80	5	6·25	0·66

It is evident that these rates do not vary in correspondence with the numbers or density of the population. Local conditions must exist, such as variations in the rainfall, different habits of life, and other factors which react on the local death-rate.

Death-rates at Different Age Periods.

Hillenberg gives in one of his papers a table (Table III.) showing the death-rates from tuberculosis per 10,000 living in Prussia at all ages. The corresponding rates per 1000, per 100,000, and per 1,000,000 can readily be calculated. Hillenberg's table shows an increase in the tuberculosis death-rates, progressing more or less regularly from the 5 to 10 age-period, to the 60 to 70 age-period, at which the maximum is reached. In the male there is a progressive increase to the 50 to 60 age-period, whereas in the female it is practically stationary between the 20th and 40th years, and after that year it sinks, except for the 60 to 70 age-period.

TABLE III.—*Tuberculosis Death-rates per 10,000 living in Prussia during the Year 1909.*

70 ,, 80	20·91	15·20	17·69

My results for Scotland for the decennium 190 1910 are different, and though presenting the actu figures in Table IV., a clearer demonstration afforded by drawing out graphic curves, t regularity of which speaks for their approxima correctness. (See Chart.) For the purpose simplifying this procedure the Scottish Direct of Medical Statistics, Dr. Crauford Dunlop, has ha the rates determined for me per 1000 living, and gladly acknowledge his kind help in these difficu calculations.

TABLE IV.—*Scotland, 1901–1910. Death-rates p 1000 Living at Different Age-periods. All form of Tuberculosis ; Phthisis ; Abdominal Tube culosis ; Malignant Disease.*

The highest death-rate occurs during the firs year of life. It then falls rapidly until the third t fourth year is reached, then somewhat more slowl to the 5 to 10 age-period. Thereafter, in the *femal* it rises slowly during the 10 to 15 age-period rapidly during the 15 to 20 age-period; and agai slowly during the 20 to 25 age-period, to reach maximum between 25 and 35; then it falls gradu ally during the later periods, the curve after the 3 to 45 age-period being slightly concave upward In the *male* the fall continues until the 10 to 15 ag period is reached; then rises rather abruptly, bu remains much lower than the female rate durin the 15 to 20 age-period. During the 20 to 25 ag period it rises above the female rate, and continue above it during the remaining age-periods, the curv having, in contrast to that of the female, it *convexity* upwards, thus indicating a very con sider able increase over the female death-rat particularly between about the forty-fifth and seventieth years.

Upon these curves I have superimposed others showing the death-rates in each sex from phthisis pulmonalis, abdominal tuberculosis, and from all forms of malignant disease. The contrast between the phthisis death-rates and the general tuberculosis death-rates is striking during the earlier years; and in the later years the apparent diminished incidence of tuberculosis on the female sex is shown to be, in part at least, accounted for by the greater number of deaths from malignant disease, not to mention the accidents of pregnancy. Whence I conclude that we should not build too much upon the apparent diminution of the death-rate in the female sex, at the later ages, which is shown in Hillenberg's table.

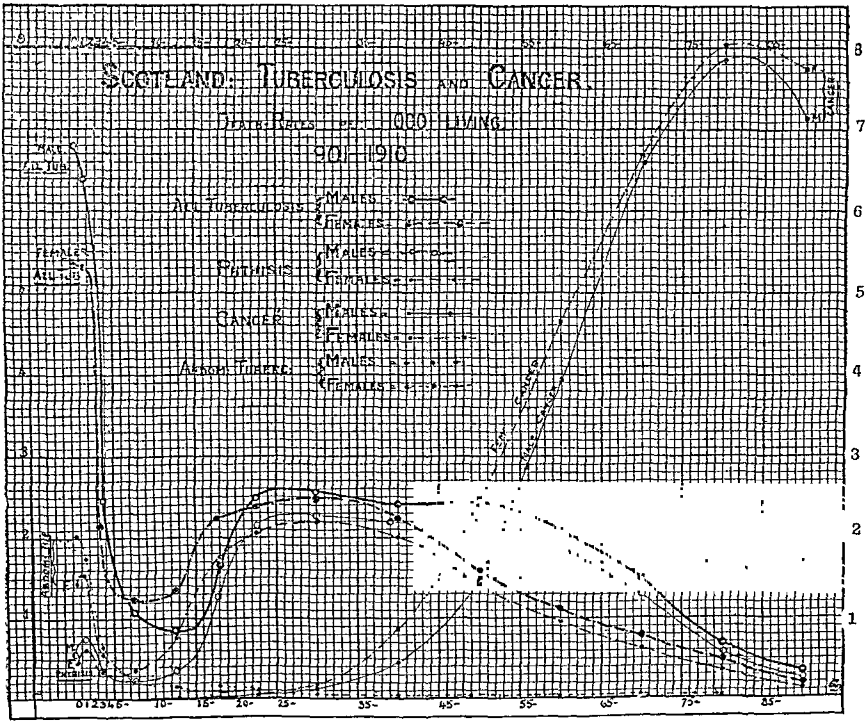

Chart showing the death-rates in Scotland during 1901-10 for tuberculosis and cancer. (See Table IV.)

The next table (No. V.) shows the tuberculosis death-rates in relation to the death-rates from all causes and at all ages. While this table is not suited for discussion but more for leisurely contemplation, I would draw attention to one fact shown by it—that is, that during the 15 to 20 age-period the female death-rate in Scotland from tuberculosis is over 50 per cent. of the total deaths in the female sex at that period. The corresponding maximum rate in the male is reached during the 20 to 25 age-period. Another feature is the rapidly progressing increase in the percentage death-rate from all forms of tuberculosis, and also from phthisis, during the successive quarters of the first year of life.

B. *Hospital Statistics.*

Following upon these general statistics I wish now to present some statistics derived from the post-mortem records of the Edinburgh Royal Hospital for Sick Children.

Although only to a modified degree applicable to tuberculosis as a disease affecting the whole country, data derived from hospital sources in large centres are, nevertheless, of great interest. In judging their value one must bear in mind that the majority of the inmates of such institutions come from the poorer and generally more badly housed and fed classes of the community. I have formerly used portions of these records for two papers, published in 1900 and 1909. For the purpose of preparing this report my successor, Dr. Carnegie Dickson, has very kindly allowed me to consult the records for the last three years, those for the period intervening between 1902 and 1910 not being immediately available.

During the periods June, 1886, to April, 1902, and December, 1910, to August, 1913, 1416 children of all ages up to the age of 14 underwent post-mortem examination. Out of that number 562, or 36 per cent., either died from tuberculosis or having died from other causes showed evidences of tuberculous infection in a latent active or latent inactive stage. Latent cases formed not more than about 4 per cent. of the total number of tuberculous cases. In point of fact, if one were to judge from experience of necropsies only, the remarkable absence of traces of tubercle in the children who died from other diseases would almost justify the opinion that practically all children infected with tuberculosis sooner or later die from that disease. This is practically the view held by Geipel.

TABLE V.—*Scotland, 1901–1910. Death-rates per cent. of Deaths from all Causes: Tuberculosis and Malignant Disease.*

The following table (No. VI.) analyses my cases, divided into the age-periods used by de Besche. The ages were given in 1277 out of my 1416 cases.

TABLE VI. (*Shennan*).

Ages	0 to 1	1 to 3	3 to 5	5 to 14	—
Total number ...	381	418	171	307	= 1277
Non-tuberculous	314	236	86	144	= 780
Tuberculous ...	67	182	85	163	= 497
Percentages ...	17·6	43·5	49·7	53·1	

Table VII. is made up from de Besche's paper.

TABLE VII. (*de Besche*).

Ages	0 to 1	1 to 3	3 to 5	5 to 14	—
Total number ...	58	28	14	34	= 134
Non-tuberculous	44	17	7	14	= 82
Tuberculous ...	14	11	7	20	= 52
Percentages ...	24·2	39·3	50·0	58·8	

Sehlbach's percentages are as follows: 0 to 1 year, 7·2 per cent.; 1 to 3 years, 26·1 per cent.; 3 to 5 years, 50 per cent.; 5 to 9 years, 47·5 per cent.

In Table VIII. my results are arranged so as to afford a comparison with H. Albrecht's percentages.

TABLE VIII.

Ages	0 to 1	1 to 6	6 to 14	—
Total number...	381	650	246	= 1277
Non-tuberculous	314	353	113	= 780
Tuberculous	67	297	133	= 497
Percentages (Shennan) ...	17·6	45·7	54·0	
Percentages (H. Albrecht)	14·6	44·0	50·0	

From perusal of these tables it will be seen that my Edinburgh results correspond more closely with those of Albrecht than with those of de Besche and Sehlbach.

Statistics presented in the above fashion are regarded as proving the statement that as age increases the incidence of tuberculosis also rises; but if my cases are separated into single year periods the appearance of a regular increase is not so evident. (Table IX.) In agreement with this result Sehlbach concludes that the percentage increase is not so regular in post-mortem cases as would appear to be the case during life from clinical observations, to judge from the results of the cutaneous (von Pirquet) and percutaneous (Escherich) reactions (Reuschel, Hamburger, McNeil).

It is probably hardly advisable to attempt to draw hard-and-fast conclusions as to the general incidence of tuberculosis from such statistics as these, particularly as they can be manipulated so as to show discordant results. I think that more correct information is afforded by the earlier tables I have given dealing with great numbers of individuals, even allowing for errors in diagnosis, the effect of which is lessened, the larger the number of the cases under review.

Particulars of the Edinburgh Cases.

In my former papers (1900 and 1909), based upon the records of the Edinburgh Sick Children's Hospital for the years 1886 to 1902, I analysed the cases of tuberculosis in some detail, but I may restate here shortly some of my conclusions and add others.

Sex incidence.—Of the children who died from tuberculosis at all ages up to 14, males predominated over females in the proportion of 55·1 to 44·8; but if these numbers are calculated in relation to the numbers of each sex dying in the hospital from all causes and examined post mortem, I find that 40·6 per cent. of the females died from tuberculosis, compared with 38·8 per cent. of the males, so that the sex incidence does not correspond with that for the whole of Scotland. (See Tables IV. and V.)

TABLE IX.

Ages	0-1	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10	10-11	11-12	12-14
Total number	381	269	149	92	79	61	58	54	38	32	25	22	17
Non-tuberculous	314	161	75	52	34	31	23	30	12	19	12	9	8
Tuberculous	67	108	74	40	45	30	35	24	26	13	13	13	9
Percentages	17·6	40·1	49·6	43·5	57·0	49·2	60·3	44·4	68·4	40·6	52·0	59·1	52·9

Of the 497 children who died from tuberculosis (Table VI.) 334 were 5 years old or under. If Cobbett is correct in stating that one-third of all cases of tuberculosis under the age of 5 years are caused by infection with the bovine bacillus, then 112 cases—i.e., 8·7 per cent. of the total number of children (1277), or 22·5 per cent., of the tuberculous cases—were infected from bovine sources. I shall, however, have more to say on this subject in connexion with tuberculosis of cervical lymphatic glands and of bones and joints.

Tuberculosis of lymphatic glands.—In the cases occurring during the period 1886–1902 the lymphatic glands showed evident tuberculosis in 83·7 per cent. The thoracic glands were affected in 69·2 per cent. and the abdominal glands in 54·4 per cent., both thoracic and abdominal glands in 39·9 per cent., the thoracic glands alone in 29·5 per cent., and the abdominal glands alone in 13·5 per cent. The corresponding figures for 1910–1913 were 69·4, 53·1, 45·0, 29·7, 15·3, 13·5. This is shown more clearly in tabular form. (Table X.)

TABLE X.

	1886-1902	1910-1913
Lymphatic glands tuberculous	83·7	69·4
Thoracic glands tuberculous	69·2	53·1
Abdominal glands tuberculous	54·4	45·0
Both groups affected together	39·9	29·7
Thoracic glands alone tuberculous	29·5	15·3
Abdominal glands alone tuberculous	13·5	13·5

These results are of interest in showing that the percentage diminution in the case of thoracic gland tuberculosis is considerable, whereas that of abdominal gland tuberculosis has remained practically stationary. An explanation of this may be found in the fact that for the last 25 years institutions (Tuberculosis Dispensary and Hospital) have existed in Edinburgh, whose efforts have been directed towards the control of open tuberculosis in man, and hence may have helped to reduce the chances of infection from human sources, though one must not forget the steady reduction in the tuberculosis and phthisis death-rates which has been going on since the middle of last century. (See also Table I.)

Relationship of tuberculosis of lymphatic glands to other tuberculous lesions.—During the 1886–1902 period, the mediastinal glands (root, bronchial, and tracheal) were tuberculous in 33 cases, or 11·7 per cent., without evidence of any tuberculosis of the lungs, whether recent or chronic. The abdominal glands (mesenteric, retroperitoneal, cœliac, and hilic) were caseous in 105 cases, or 47·5 per cent., without any ulceration of the intestines and in 73 cases, or 33 per cent., without any excavation of the lungs. Ulceration of the intestine without excavation of the lungs was found in no fewer than 111 cases, or 22·5 per cent., of the whole series (1886–1902 and 1910–1913). Taking the whole number of tuberculous cases, 497 (Table VI.), the immediate cause of death was tuberculous meningitis in 228 cases, or 45·8 per cent.

These statistics prove again what I have always held—viz., that statistics showing the incidence of tuberculosis in any one country or city must not be accepted as wholly applicable in the case of any other country or city. I wish to emphasise this point very strongly, as it is constantly disregarded.

The Nature and Modes of Infection in Tuberculosis: General Considerations.

Before passing on to discuss the morbid anatomy of tuberculosis in relation to infection in that disease, I must refer to Cornet's localisation law, and consider whether any alteration of opinion with regard to that law is necessary in view of recent work upon the nature and course of primary infections, secondary infections, and reinfections, upon hypersensitiveness (allergy) and immunity, upon latency of tubercle bacilli and lymphoid hyperplasia.

Cornet's localisation law.—This law, which has been recognised more fully on the continent than in Great Britain, states that the portal of entry, at least in tuberculosis, is invariably indicated by the fact that a primary lesion is produced at the point at which the infective agent has invaded the body, as well as by the concomitant disease produced in the regional lymphatic glands of the organ first attacked, and which are therefore related to the point of entry.

Many important authorities now maintain that the facts which have been disclosed in connexion with the development of increased susceptibility to infection, following a primary inoculation with a bacterium, have so profoundly altered our conception of the course of an infection that Cornet's law no longer holds, or at least that it requires to be modified in important respects.

Primary and secondary infections and re-infections, hypersensitiveness, &c.—Bartel and Neumann, Hart, and others state that if an experimental animal already inoculated with tubercle bacilli be injected with virulent tubercle bacilli the resulting disease takes a course quite different from that taken by a first infection. For example, secondary metastatic lung tuberculosis can be produced under these conditions without an appreciable lesion at the point at which the secondary infection has taken place, the lungs having apparently become very susceptible to metastatic infection, whereas the rest of the body has become increasingly resistant. Arguing from these experimental results, these authors conclude that, as doubtless human phthisis in most cases develops in an organism which has been already *once* infected, the post-mortem appearances can no longer be trusted to decide the portal of entry of the virus. With Oettinger and Wittgenstein they hold that the lungs react, even though only a few bacilli reach it. Austrian comes to a similar conclusion. On the other hand, Hamburger, Römer, Sata, and others maintain that a small reinfecting dose is of no effect in producing disease, that diminished infectiveness is shown to a moderate-sized reinfecting dose, but that immunity is actually decreased to a large reinfecting dose of bacilli.

Latency of tubercle bacilli.—The above question is associated with the fact, which is now well recognised, that tubercle bacilli may lie latent in the lymphatic glands, possibly for long periods of time (von Behring, Weichselbaum, Bartel, Harbitz), and these authors state that a reinfection may occur from these glands without visible histological changes in the gland tissue. But Beitzke shows that a spread of tubercle bacilli by the blood stream never takes place in the child during the latent stage, or it occurs only under exceptional circumstances. In his positive cases the latent bacilli were always found in glands which drained a possible portal, and never in peripheral glands; hence those glands could not have been infected through the blood stream. Further, Beitzke has never succeeded in demonstrating the presence of latent bacilli in the lymphatic glands in children without being able at the same time to detect, either with the unaided eye or with the microscope, evidences of their presence and action, and he concludes, apparently with good reason, that an isolated tuberculosis, wherever it is situated, indicates with great certainty the portal of entry. Joest and Emshoff agree with him that in experimental animals true latency of tubercle bacilli in lymphoid tissue cannot be proved, seeing that they could always detect histological changes. Steffenhagen and Ungermann consider that latency in glands is rare in childhood. Whipple found that bacilli which had penetrated the mucous membranes without producing visible local lesions caused disease in the regional glands in the great majority of instances. One must bear in mind that in the human subject the regional glands are much more numerous than in the ordinary experimental animals, and constitute a succession of barriers to invasion, tending to act, particularly in the child, as a bacteria-proof filter. There is also justification for the belief that the longer the bacilli lie latent the greater is the tendency for their virulence to diminish, although other recognisable characteristics may remain unaltered (Kossel, Weber and Heuss; Weber and Steffenhagen; Neufeld, Dold, and Lindemann; Gratia, Moeller, Lignières, and others), a state of active immunity, doubtless imperfect in most cases, being in the meantime gradually established. I would also suggest that we should not neglect to consider the possibility that in natural human infections virulent bacilli lying apparently latent in lymphatic glands may have entered the body recently—more recently, in point of fact, than is indicated by the age of tuberculous processes already present in the body. Natural infection in tuberculosis is often a repeated infection by small numbers of bacilli.

For the above reasons, therefore, excluding cases in which a generalised blood infection has involved the lymphatic glands simultaneously with the other organs and tissues of the body shortly before the fatal event, I would conclude that a tuberculosis of lymphatic glands indicates an infection from the portal or organ drained by them; and that usually the primary portal of invasion is indicated by the greater age of the tuberculous process in its regional glands. One cannot equally affirm the invariable correctness of the other part of Cornet's localisation law—viz., that a local lesion is always found at the point of entry, it being now generally conceded that tubercle bacilli can penetrate an apparently normal mucous membrane without leaving a trace of their passage. The important observations on allergy, or hypersensitiveness, contributed chiefly by the Vienna school, afford an explanation of the views, already strongly held and fully appreciated, that a tuberculosis of the bronchial glands does not necessarily in every case locate the primary portal of infection in the lungs, seeing that infective agents, at whatever point they enter the body sooner or later reach the lungs and their regional glands. Similarly it is recognised that a tuberculosis of the mesenteric glands, either with or without ulceration of the intestine, is not always of necessity a deglutition tuberculosis. Hence, while I cannot admit the correctness of Baumgarten's view that an inhalation tuberculosis is never a primary pulmonary tuberculosis, but a generalised tuberculosis, I believe that a primary infection, in addition to causing the lesions in the regional glands guarding the portal of entry, may be followed by a lymph-hæmic spread and development of tuberculous foci, it may be of somewhat chronic course, in different organs. This would, for example, explain those puzzling cases in children in which isolated and contemporaneous, chronic, caseous, or fibro-caseous foci are found in lungs, kidneys, spleen, liver, and occasionally in the meninges, in association with the rapidly progressive recent lesions which have brought about death.

Lymphoid hyperplasia.—Bartel was the first to direct attention to the fact that one of the first results of invasion of the lymphatic glands by tubercle bacilli was a hyperplasia, and he regards this change as somewhat characteristic; but Beitzke demonstrated clearly that other causes can produce the same alteration, and while admitting that a relationship undoubtedly exists between tuberculosis and lymphoid hyperplasia, he claims that the latter is not pathognomonic of tuberculosis. Otherwise one might be tempted to assume a relationship between lymphatism also and tuberculosis. There seems to be no doubt that the lymphatic glands are especially prone to tuberculosis (Steffenhagen, de Besche, H. Albrecht, Ely, Rillet and Barthez, Guthrie, Still, Shennan, Leslie, Burckhardt, Stirnimann, Engel, Escherich, Hamburger, Kossel, Finkelstein, Lapage and Mair, and others). As a matter of fact, tuberculosis of the child is generally regarded as essentially of the nature of a tuberculous lymphadenitis. Possibly this predisposition may be more apparent than real, seeing that guardians of a portal, under ordinary conditions thoroughly efficient, may be overcome by an excess of an invading host.

Baumgarten, Bongert, and Oehlecken succeeded in infecting lymphatic glands by way of the blood stream in the case of experimental animals. Huguenin reports a remarkable case of generalised tuberculosis of the lymphatic glands in a woman 82 years of age, the other organs of the body being apparently unaffected.

The Portals through which Tubercle Bacilli Invade the Human Body.

Tubercle bacilli may enter the body at any part of the cutaneous surface, or at any point in the various (internal) channels and passages communicating with the surface. The cutaneous and genital route (inoculation) is seldom taken, and of the internal channels the respiratory and the alimentary tracts afford the readiest access to the body. Before one may attempt to determine which of these two is the more important, it is essential to have accurate knowledge of the finer anatomical relationships of these tracts to the lymph- and blood-vascular systems, and it is also essential that the conclusions drawn must be in harmony with what we know of general pathological processes in man and of infection generally. I am afraid that a considerable amount of the almost overwhelming literature on tuberculosis, if submitted to these tests, would have to be rejected.

The respiratory tract.—Seeing that most authorities agree that the tubercle bacillus enters the human body most easily and most frequently through some part of the respiratory tract, it seems fitting to discuss this portal first. In doing so it will be necessary to refer to opposing views as to the greater importance of invasion by way of the alimentary tract, and perhaps it will be better to focus attention on the question of the portals of invasion in tuberculosis of the lungs and their regional glands (the bronchial glands, including the hilic or root glands).

This question has been the one most debated of recent years, and the alteration in the general outlook of many writers upon this subject illustrates the remarkable extent to which the pendulum of authoritative scientific opinion may swing in *diametrically opposite directions.* Before 1903, when von Behring presented his views on the universality of alimentary infection during early life, and on the latency of tuberculous infection. and the elaboration and extension of these views by Baumgarten, Weichselbaum, Bartel and Neumann, Ritter and Vehling, Calmette and his followers, Vansteerberghe and Grisez, Guèrin, Whitla, and many others, everyone believed that pulmonary tuberculosis was the result of an air-borne and respiratory infection, except in certain cases in which it was metastatic—i.e., secondary to a primary tuberculosis elsewhere in the body. But now some authors, some of whom I have mentioned, hold that the portal of primary invasion in man in tuberculosis is *always* the alimentary tract, and that tuberculosis of the lungs is invariably lymph-hæmic in origin, and never directly aerogenic. In all vocations and activities of life extreme views, though often undoubtedly leading to progress, are not infrequently found to be unsafe guides. Tuberculosis, I submit, cannot be an exception to this rule; as has already been shown, in point of fact, in connexion with the view that man never suffers from bovine tuberculosis. It is evident, as Bulloch puts it, that the question is not so much one of aerogenic *versus* ingestion or deglutition, as of aerogenic *versus* lymph-hæmic invasion of the lungs and bronchial glands, and I may proceed to state the arguments supporting or opposing the different main theories.

Aerogenic infection.—Till comparatively recently, and, I think, depending on some old experiments of Pasteur, it was held that if air be respired through the proper channels—that is, through the nasal cavities—to the lower respiratory passages it reaches the pulmonary alveoli in a sterile condition, the organisms and other suspended particles being deposited mechanically on the surfaces of these channels. Arguing on the same lines, while not denying that air, inspired by individuals who live in close association with open cases of pulmonary consumption, does contain tubercle bacilli, many authorities hold that these bacilli do not reach the *ultimate bronchioles and vesicles, but become* entangled in the mucus of the bronchi, and being carried upwards in this are swallowed or expectorated by the individual. While granting that this does take place, there seems absolutely no reason to doubt that tubercle bacilli, entering with the inspired air, can and actually do succeed in reaching the vesicles. Many experimenters—e.g., Beitzke and Cobbett—have clearly demonstrated that dust particles and bacteria (e.g., B. prodigiosus) can readily penetrate to the ultimate air passages and vesicles. Further, the balance of opinion is on the side of the view that guinea-pigs and cattle can be more readily infected with tuberculosis in inhalation experiments than in feeding experiments and with a comparatively small number of bacilli.

The pneumonoconioses.—Passing away from tuberculosis for a moment, let us now consider the manner in which the lungs become pigmented in the pneumonoconioses or "dust diseases." In the case of anthracosis or coalminers' lung all the evidence from the side of morbid anatomy favours the aerogenic origin of the pigmentation in the human being. Even granting that Calmette and his followers are correct in holding that pulmonary anthracosis can be developed in laboratory animals by feeding with carbon, except in the case of very young animals, why is it that in man, at whatever *age the body be examined, so little evidence can be* found of the passage of carbon through the intestinal walls and through the mesenteric and retroperitoneal lymph nodes? No doubt in the adult one occasionally sees accompanying extreme pigmentation of the lungs some moderate carbon pigmentation of the glands above the lesser curvature of the stomach, but similar pigmentation of the *mesenteric* glands at any stage of pulmonary anthracosis is very rare, if indeed it ever occur at all to any appreciable extent. The amount of carbon pigmentation of the cœliac and hilic glands can readily be explained by the absorption from the upper part of the alimentary tract of minimal quantities of the carbon which has been swallowed entangled in the mucus of the respiratory tract, or which has been conveyed by lymphatics from the pleura over the surface of the liver to the hilic glands. The abdominal pigmentation is of secondary importance and certainly does not indicate a primary alimentary portal.

A still stronger argument can be deduced from the morbid anatomy of silicosis or lithosis of the lungs—stonemasons' lung. This disease, as is well recognised, predisposes to tuberculosis, and Cesa Bianchi has demonstrated that it is easier to infect guinea-pigs with tubercle bacilli after they have been made to inhale different kinds of dust, but at present I am concerned with silicosis as a dust disease only. In the most extreme case of silicosis I have seen, in which I had to use the saw to make sections of the lungs, I found considerable pigmentation and condensation of the hilic and cœliac lymphatic glands, but no similar changes were found in the mesenteric and lower retroperitoneal glands. One cannot accept the view that these abdominal glands could possibly have permitted the passage of such quantities of siliceous and carbon particles as were required to produce the stony hardness and dense pigmentation of the lungs and bronchial glands. As a matter of fact, no one seriously denies that the lung condition in silicosis is directly due to aerial convection of the siliceous particles. Another important point is that the area *of greatest condensation of the lung in silicosis* extends from the root upwards and outwards, just in the position in which tuberculosis so often attacks the lung in early adult life. Silicosis is certainly aerogenic, why not tuberculosis, at least in the adult?

Again, supposing that in primary pulmonary tuberculosis the infective agent is invariably carried to the lung in the blood stream, then we should expect in most cases to find the two lungs with their regional glands affected to an approximately equal extent, but this is not usually the case in man, even in the child. Both Still (1901) and I myself (1900) independently remarked the greater prevalence of tuberculous caseation of the bronchial glands on the right side. Albrecht has also noticed the same feature. Out of 183 cases I found the glands more affected or alone affected on the right side in 123 (67·2 per cent.); and in 60 cases (32·8 per cent.) those on the left side showed either a more advanced tuberculosis or were alone affected. It has been absolutely proved (Beitzke, Hart, Most, and others) that these glands are the regional glands of the lungs, Weleminsky's theory that the bronchial glands act as a sort of lymph heart, receiving all the lymph of the body by special channels from the upper and lower parts of the body, having now no authoritative support.

Even in view of the anatomical fact that the glands related to the right bronchus are more numerous than those related to the left bronchus, we have to explain the greater tendency of tuberculosis to attack these right bronchial glands as a group.

Furthermore I find that out of 127 cases of excavation of the lungs in children under the age of 15, in 28 per cent. the cavity or cavities were limited to the left lung, in 42 per cent. to the right lung, while in the remaining 30 per cent. both lungs were affected. Taken along with the greater prevalence of tuberculosis of the regional glands of the right lung, this affords another strong argument against the hæmic origin of pulmonary tuberculosis as being the rule. I have ascertained that in Edinburgh the medical officers connected with the Victoria Tuberculosis Hospital and Dispensary find that phthisis pulmonalis more often begins on the right side. In the child the slightly greater size of the right lung is insufficient plea to advance against my argument, and there is absolutely no reason to suppose that the right lung rather than the left is a *locus minoris resistentiæ*. I should also expect that the distribution of the lesion in a blood infection would more regularly bear a close analogy to that of the abscesses and embolic infarcts in cases of pyæmia. The capillaries of the lungs are the widest in the body, and they allow small emboli to pass through, which are subsequently caught in the smaller capillaries, for example, of the kidney. Now renal caseous tubercles are by no means commonly found at post-mortem examinations, except in young children.

I am, therefore, forced to the conclusion that in the adolescent and adult a hæmic infection of the lungs is by no means so important as the aerogenic infection in the vast majority of cases of pulmonary tuberculosis. It is reasonable to suppose that the tubercle bacillus, like other morbific agents in nature, takes the shortest route and the line of least resistance to reach its goal, and in the case of the lungs this route is the aerial.

But, while to my mind the above conclusions are rational and true, they by no means exclude the hæmic route as a channel by which the lungs may be attacked, particularly if hypersensitiveness has developed, and especially in children. For the settlement of this difficult question the work of Weichselbaum, Bartel and Neumann, and that of Calmette and the French school generally, afford us real assistance, because it is difficult to understand why the lungs should be so vulnerable. At first sight one would suppose that these organs, constructed as they are of fibrous and elastic tissue, covered with strongly phagocytic epithelium and endothelium, and richly supplied with blood through both the pulmonary and the bronchial arteries, should be highly resistant to the attacks of an organism like the bacillus tuberculosis, to which man as a class has developed some measure of immunity.

Hart and Cobbett maintain that the lymphatic glands guarding the alimentary portal are better trained in defence against organismal invasion than are those guarding the respiratory portal. As Hart says, the former have been the battleground (Tummelplatz) of countless millions of organisms, whereas the barriers to be crossed before organisms can enter the respiratory tract are so efficient that few of them reach the bronchial glands to train them to resistance. This is true to a certain extent, but is not sufficient to explain the great frequency of tuberculosis of the respiratory tract, and, further, Calmette claims that, when properly administered, no greater number of bacilli are required to cause an alimentary infection than a respiratory one.

The true condition of matters would seem to be that in primary lung tuberculosis there is no special hypersensitiveness of the lungs to tuberculous infection, but that primary infections are due to long-continued attacks of tubercle bacilli, whether from the air or from the blood. The conditions are altered, however, when hypersensitiveness has developed. Robert Koch was the first to show that an animal after being infected once with tuberculosis becomes more susceptible to the action of the same organism when reinjected. This doctrine has been elaborated by von Pirquet, Weichselbaum, Bartel, and others, and is now well recognised under the name of allergy given to it by von Pirquet. It is unnecessary to discuss the relationship of allergy to immunity. It will suffice to say that many believe that an extremely small dose of the infective agent on reinoculation may increase the resistance, while a considerable reinfecting dose leads to severe pathological changes, with, in the guinea-pig, tuberculosis of the lungs, as well as the tuberculosis of the spleen which commonly follows a primary infection. Austrian maintains, in opposition to the above, that even a minute reinfecting dose may cause severe pulmonary changes in an allergic animal. Bartel and Neumann regard the lung in every form of tuberculous infection as a *locus minoris resistentiæ*. H. Albrecht refers to the possibility that a widespread interference with the lymphatic circulation may render the thoracic organs more liable to infection by the production of a *habitus phthisicus*.

The date of reinfection is evidently of importance, and if a considerable reinfection occur comparatively shortly after a primary infection it will ordinarily be followed by rapidly progressing tuberculosis, and apparently the resistance of the lungs especially is reduced. This would explain the extensive and rapidly progressing caseous pulmonary tuberculosis which we so often see in early childhood, in many cases spreading into the lung from caseous root glands.

This does not exhaust the possibilities in childhood. I believe that in early years a lymph-hæmic infection of the lung is not uncommon; but in view of what I have already said one must walk warily, and consider not merely the condition of the lungs as seen post mortem, but also that of the other organs, and especially the solid abdominal organs. I have observed in many cases of tuberculosis in infants that small caseous or fibro-caseous nodules occur in small numbers in the spleen, kidney, liver, in one or both lungs, and occasionally in the meninges.

These are only very exceptionally associated with excavation of the lungs, either recent or advanced. They may be associated with tuberculous ulceration of the intestine, but more often accompany tabes mesenterica and tuberculosis of the bronchial glands. The nodules in the lungs may be located at any point, but are frequently peripheral. Now this association of contemporaneous foci in widely separated organs must indicate a blood or lymph-*hæmic infection.*

Very little, so far as I know, has been done in the way of determining, by animal inoculation and separation of the causal organism, the type of the bacillus causing these lesions and its probable portal of entry. The other aspect of the question is also interesting—namely, how seldom these caseous foci appear to be associated with pulmonary excavation, and this problem also deserves further attention.

In these cases it is not permissible to regard the caseous or fibro-caseous pulmonary focus as necessarily the primary focus in the body, and I think H. Albrecht is in error in doing so. It also raises the question whether, even if one finds a small chronic focus in the lungs, one can state dogmatically that this is the focus from which the bronchial gland tuberculosis also present has originated. This may be due to a separate new aerogenic or lymph-hæmic infection.

(To be concluded.)

A COMPARISON OF THE ACTIONS OF CHLOROFORM AND ETHER ON THE BLOOD PRESSURE.[1]

BY H. P. FAIRLIE, M.D. GLASG.,
ANÆSTHETIST TO THE ROYAL AND WESTERN INFIRMARIES, GLASGOW.

SINCE dealing briefly with this subject on a former occasion,[2] when my remarks were confined entirely to the action of the two anæsthetics during their administration, I have endeavoured to follow up my observations and to extend them *to the period subsequent to operation.* The result of those observations is a corroboration of the view which I previously expressed—viz., that in presence of severe shock chloroform anæsthesia is preferable to ether. In support of this the blood pressure observations of which I am going to make use are taken from a series of 211 cases, of which 120 are chloroform administrations and 91 ether administrations. Wherever practicable one or two readings have been made some time previously to operation, one reading on the patient's arrival in the theatre, and as frequent readings as possible [illegible] t has often been difficult [illegible] early part of the adminis-[illegible] as the disturbing effect on the patient, during struggling it has not been possible. Latterly, in addition to those readings, observations have been continued for some time after the operation—for 48 hours, or in some cases longer.

The instrument which I used in estimating the blood pressure was Martin's modification of the Riva-Rocci sphygmomanometer, and in all cases the systolic pressure is referred to.

In classifying anæsthesia I have made use of four stages: (1) the stage of excitement; (2) the stage of light anæsthesia; (3) the stage of surgical anæsthesia; and (4) the danger stage.

It is necessary to preface my remarks on the blood pressure by pointing out that it is influenced by causes other than the action of the anæsthetic. The principal of these are shock and collapse. Crile defines shock as "a condition resulting from a fall in general blood pressure due to exhaustion of the vaso-motor centres," and collapse as "a condition resulting from a fall in the general *blood pressure due to inhibition of the vaso-*motor centres or a loss of the circulation fluids." Mummery, in his Hunterian lectures,[3] stated that "shock may be produced in two main ways: (1) by injury to important afferent nerve paths; and (2) by exposure or injury of the abdominal viscera." He further points out that the former of those two causes may at first cause a rise of blood pressure, due to stimulation of the pressor fibres which sensory nerves contain, but later, on those becoming exhausted, a fall, due to stimulation of the depressor fibres; and also that no structural changes accompany shock, as evident from the fact that no lesions are found in persons dying from shock, and that when recovery takes place it is complete.

As to the direct action of the two anæsthetics on the blood pressure, independently of intercurrent factors, based on experimental and clinical observations there is unanimity of opinion that chloroform causes a fall, but that the effects with ether vary, no very pronounced change taking place. The following charts are a very few examples, taken from typical cases, illustrating the behaviour of the blood pressure under the two anæsthetics. The illustrations have been divided into two classes, those in which the operation involved a slight degree of shock, and those in which it involved a severe degree of shock.

1. *Cases in which the Operation Involved a Slight Degree of Shock.*

(*a*) *Chloroform.*—In this class the blood pressure, after the fall which accompanies the induction of anæsthesia, remains at about the same level until the latter part of the operation, when, along with a less deep anæsthesia, it begins to rise again. For some hours after the operation there is usually a slight drop, followed by a rise to a point a little below the patient's normal.

CASE 1.—A man, aged 56, a moderate drinker. Arteriosclerosis; chronic bronchitis. Heart: Loud second sound at aortic area; no murmurs. Operation: Cystotomy; removal of papilloma. Anæsthetic: Chloroform on open mask, then by Vernon Harcourt inhaler; 35 minutes. After violent struggling during induction the pressure fell 68 mm. At this point the anæsthesia was very deep, and with a lighter anæsthesia the next reading was 23 mm. higher. Towards the end of the operation a further rise took place. One hour after the operation the pressure had risen to a point about the patient's normal. Then, four hours after the finish of the operation, a considerable fall took place, followed by another rise. There was some hæmorrhage after the operation. (See Chart 1.)

---

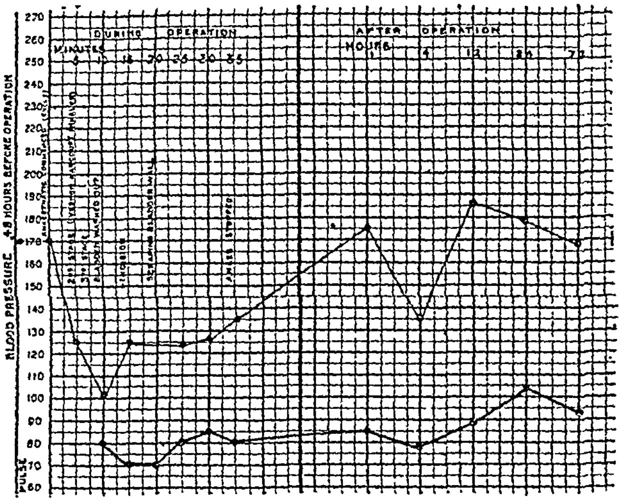
[2] Practitioner, February, 1911.

[3] THE LANCET, March 18th (p. 696) and 25th (p. 776) and April 1st (p. 846), 1905.

In this case the pulse became slower with a falling blood pressure. It is very unusual to get such a pronounced fall in blood pressure as occurred in this case, though patients whose normal blood pressure is high usually show a marked fall with the induction of anæsthesia by chloroform. This patient's pressure 48 hours before operation was 170 mm.

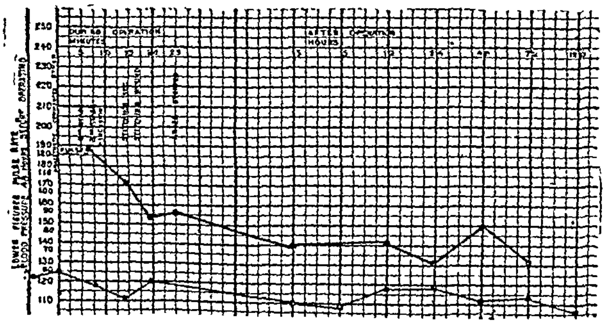
Chart 1.



(*b*) *Ether.*—The induction of anæsthesia is not usually marked by any pronounced change in the blood pressure level. There may be a slight rise or a slight fall. In this first class where the operation causes little shock the early part of the operation is usually accompanied by a slight fall, after this the pressure remaining fairly constant. Afterwards the pressure rises to a point near the patient's normal.

Case 2.—A man, aged 24. Heart and lungs normal. Operation: Radical cure of inguinal hernia. Anæsthetic: Ether by Clover's inhaler; 26 minutes. The pressure fell slightly during induction and again 7 mm. early in the operation, rising slightly towards the end of anæsthesia. Afterwards the readings were a little lower until at 12 hours a rise was recorded almost to the normal level. The pulse-rate fell very decidedly during anæsthesia, much more than is usual with ether. (See Chart 2.)

Chart 2.



It will be noticed that the reading taken on arrival in the theatre is higher than that taken on the day previous to operation. This is the rule in most cases and is probably to be attributed to nervousness. Janeway says that "mental excitement is the most powerful cause of increased pressure in the normal man."[4]

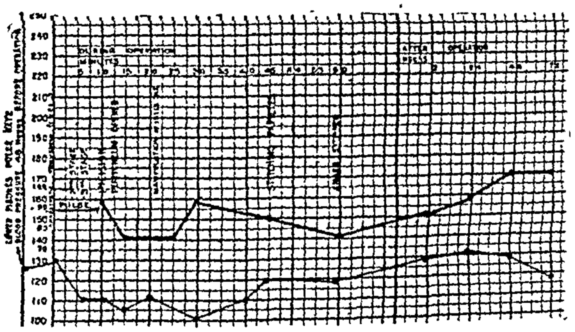
2. *Cases in which the Operation Involved a Severe Degree of Shock.*

The best illustrations of this class of cases are abdominal sections, as any intra-abdominal manipulation is productive of shock.

(*a*) *Chloroform.*—After the initial fall of blood pressure due to the anæsthetic any surgical procedure causing shock produces a second fall. The pressure remains low during the early part of the operation, beginning to rise with the closing of the wound. The early readings after operation usually indicate a slight fall, then a gradual rise takes place to about the patient's normal level.

Case 3.—A stout, nervous girl, aged 25. Heart and lungs normal. Operation: For ventral hernia. Anæsthetic: Chloroform on an open mask; 58 minutes. The excitement stage was accompanied by struggling and screaming. The fall in blood pressure after the peritoneal incision was small; during the manipulation of viscera, however, a decided fall was observed. Following this there was a progressive rise. Unfortunately very few readings could be taken after operation, none being taken between 2 and 24 hours. Both indicated a progressive rise. (See Chart 3.)

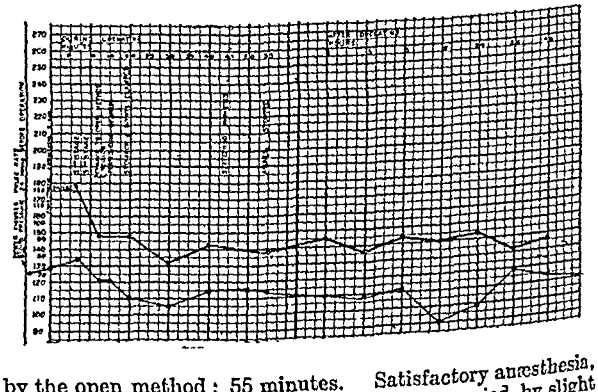
Chart 3.



(*b*) *Ether.*—As a rule, the level reached by the blood pressure in the early stages of surgical shock during ether anæsthesia is not so low as during chloroform anæsthesia. But as the operation advances, and towards its finish, there is a tendency for the pressure to remain low or even to go lower; and during the early hours after the patient's return to bed this downward tendency is still in evidence, there being often an interval of 12 hours or more before a rise commences.

Case 4.—A well-built but somewhat ill-nourished man, aged 32, a moderately heavy drinker. Heart and lungs normal. Operation: Gastro-enterostomy for dilated stomach. Anæsthetic: Ether by Clover's inhaler for 12 minutes, then by the open method; 55 minutes. Satisfactory anæsthesia, the induction, lasting eight minutes, accompanied by slight struggling. At 11 minutes, just before the incision, the blood pressure had fallen 8 mm. (after a preliminary rise). During the first part of the operation there was a fall of

Chart 4.



---

[4] The Clinical Study of the Blood Pressure, p. 119.

15 mm., then, during the latter part of the stitching of the [illegible] rise of 10 mm., the level then [illegible] five minutes before the finish [illegible] ading in the theatre indicated a slight fall, and this was continued afterwards. Nine hours after the operation a very decided fall to 90 mm. occurred. From this point there was a rise. (See Chart 4.)

I will now sum up the effects of the two anæsthetics on the blood pressure.

(*a*) *Chloroform.*—A fall of pressure is produced throughout the administration of chloroform. With the establishment of full anæsthesia this fall amounts to at least 10 mm. and sometimes considerably more; along with this the pulse beats slower and a varying degree of pallor is present. Surgical shock during chloroform anæsthesia produces a slight further fall of pressure. With the withdrawal of those two depressants—chloroform and shock—the blood pressure exhibits a tendency to rise rapidly, and very often soon reaches a point a few millimetres below the patient's normal.

(*b*) *Ether.*—Little alteration of the blood pressure is produced by ether. It may cause a rise, it may maintain a constant level, or it may cause a fall. It causes more rapid and more forcible cardiac action, with dilatation of the smaller vessels (as evidenced by the flushing which occurs), the latter probably counteracting the former in maintaining the blood pressure level almost constant. With intercurrent shock a considerable fall of pressure takes place, a fall almost equal to the combined effects of chloroform and shock. The subsequent recovery after severe shock is slow, some time elapsing before the blood pressure approaches the normal level.

What influence do those considerations have in the choice of the anæsthetic? In answering this question it is again necessary to differentiate with regard to the nature of the operation into (1) those cases in which only slight surgical shock is to be anticipated, and (2) those cases in which severe shock is to be anticipated.

1. *In slight surgical shock.*—In all cases chloroform causes considerable lowering of the blood pressure, whereas, in this class of cases, there is but little lowering of the blood pressure under ether. With the latter anæsthetic, therefore, the margin of safety is greater than with the former. In this class ether is the anæsthetic of choice.

2. *In severe surgical shock.*—At the end of an operation in this second class the blood pressure shows more tendency to reaction with chloroform than with ether, there is a more decided and better maintained rise with the former. This consideration, it seems to me, should go a long way as a guide to the choice of anæsthetic. At a time when it is of vital importance that patients should be able to make use of all their resources, after chloroform anæsthesia they are better able to do so than after ether.

I do not wish to ignore in any way the danger of chloroform as evidenced by the rapid fall of blood pressure which it produces, particularly in the early stages of its administration. The only death under anæsthesia which I have had occurred under chloroform eight minutes from the time of commencing the administration, and before the operation had been commenced.[5] This case and other less serious experiences have been quite sufficient to impress upon me the care which is necessary in making the choice of anæsthetic, and in the use of chloroform where it is chosen.

But there is another point of view, and one the value of which it is much more difficult to estimate. I mean the relative safety of the two anæsthetics with regard to the period immediately succeeding operation. Is it not possible that the anæsthetic may play a part in causing or averting death in the period subsequent to operation, as well as in the chances of rapid recovery? It must also be remembered that the chloroform danger can be lessened by employing ether for inducing anæsthesia, in this way getting over the most dangerous part of the administration. Under those circumstances a change to chloroform produces a less decided fall of blood pressure than where chloroform is used throughout.

After weighing up all those considerations I think that, in this second class, chloroform is the anæsthetic to be chosen; the induction of anæsthesia, however, being effected by means of ether. In this paper it must be understood that I am only considering the two anæsthetics as they affect the circulation, and especially as they affect the blood pressure.

The observations which led up to those conclusions extended over a period of three years, and were quite independent of work done by others, as only latterly have I consulted the literature on the subject. I find that most of the writers have formed conclusions entirely opposed to my own. At the same time, all the writers whom I have consulted base their opinions on the fact that during anæsthesia chloroform produces a fall in blood pressure, ether does not; and as far as I have been able to discover no one has continued observations on the behaviour of the blood pressure subsequent to operation.

Mummery made a series of observations on blood pressure during operation.[6] From these he came to the following conclusions:—

> There is a marked rise in the blood pressure in the early stages of ether anæsthesia, and the net result of all the investigations into the effect of ether anæsthesia upon the blood pressure shows that it tends to remain at its normal level or to be raised slightly throughout the whole period of anæsthesia, any fall in blood pressure which occurs during an operation being due to the steps of the operation and not to the anæsthetic.
>
> With chloroform anæsthesia the results are almost the exact opposite of those with ether anæsthesia. It has always been the opinion of London surgeons that ether anæsthesia is safer in long operations and those where shock is anticipated than chloroform anæsthesia. *This fact, based* upon clinical observation, is proved beyond all shadow of doubt by blood pressure records of operations. Chloroform anæsthesia is accompanied by a fall in blood pressure during *the whole anæsthesia.*

Walton,[7] following up Mummery's investigations, agrees with his main conclusions. In dealing at the same time with the treatment of shock, however, he makes a statement which, it seems to me, is quite contradictory: "In no case should any form of stimulant, either brandy, strychnine, or ether, be administered previous to or during the course of an operation." He then goes on to state that the administration of such stimulants leaves the patient in worse condition than if they had not been given. So that, while disapproving of ether as a stimulant, he recommends it as an anæsthetic on account of the fact that it is a stimulant.

Barton,[8] speaking of the open method of ether administration, says: "*Given in this way ether* has the advantage over chloroform in that it is safer and tends to the prevention of shock during operation."

[8] Practitioner, November, 1910.

Blumfeld[9] refers to the same subject: "Thus ether tends to keep up blood pressure, and thus to diminish surgical shock. Chloroform, on the other hand, throughout an administration tends to cause a lowering of blood pressure, and thus adds an additional degree to any surgical shock that may be caused by an operation."

In nearly all the literature too much emphasis seems to be placed on the conditions obtaining during anæsthesia and too little on the subsequent state. Dudley Buxton,[10] however, in an article on the relative merits of chloroform and ether in operations for exophthalmic goitre, refers to the latter point: "Though he had employed chloroform he was ready to believe that the open ether method or venous infusions of ether were useful methods. In the latter, however, there was a danger of collapse when the unnatural stimulation of the ether passed off." The same writer[11] in a biographical article on Long, the discoverer of the anæsthetic properties of ether, makes a similar reference: "The very safety of the drug (ether) became its chiefest danger, since etherists were so obsessed by the fact that ether does not lower blood pressure or cause cardiac collapse through depression, that they failed to recognise the perils incident to over-stimulation, especially in asthenic persons."

Brown[12] writing on "Post-operative Shock," after pointing out that shock is due to exhaustion of the cells in the vaso-motor centre, claims that chloroform narcotises these cells and in this way prevents their energy being used up during shock, so that with the withdrawal of the chloroform they regain their activity. Ether, on the other hand, he thinks, does not possess this narcotic effect on the vaso-motor cells, and may even act on them as a stimulant. In summing up he says:—

> And the conclusion to which I am led is that while ether is undoubtedly the safer anæsthetic so far as the time during which the patient is under its influence is concerned, as regards the after-effects shock is more likely to be lasting and serious when ether has been used for a prolonged operation than if we had recourse to chloroform and kept the vasomotor cells partially narcotised.

The last quotation is in agreement with my own observations. Based on those observations I think that ether is the anæsthetic of choice for short operations or for those operations where little shock is anticipated, while chloroform is better for prolonged operations and for those where considerable shock is anticipated.

LONDON SCHOOL OF TROPICAL MEDICINE.—Dr. R. T. Leiper, helminthologist of the London School of Tropical Medicine, Surgeon E. L. Atkinson, R.N., who has been seconded by the Admiralty, and Mr. Cherry-Garrard (both of whom accompanied the Antarctic expedition) have started on an expedition to the Far East with the object of ascertaining the mode of spread of trematode diseases of man, especially bilharziasis. Investigations will also be made into ankylostomiasis, which has wrought great havoc among the coolies on the tea and rubber estates. The expedition has been subsidised by a grant from the Colonial Office, and the United States Rubber Company have offered facilities for the study of medical problems on their estates in Sumatra.

A CASE OF CHRONIC JOINT LESIONS IN HÆMOPHILIA.

By D. W. CARMALT JONES, M.D. Oxon.,
PHYSICIAN TO WESTMINSTER HOSPITAL.

ALL writers on hæmophilia emphasise the importance of joint lesions as being among the most frequent, painful, and disabling conditions incident to the disease. Wickham Legg[1] observed that the large joints were chiefly affected, that they became painful, swollen, and full of fluid, and that the fluid sometimes disappeared rapidly in a few days, and sometimes persisted for weeks or months, and also that the effusion frequently recurred. Sir Almroth Wright[2] states that articular effusions occur in practically all cases as soon as active exercise affects the joints, and that the fluid is chiefly clear lymph with or without the addition of red corpuscles; this fluid is not completely absorbed, adhesions occur together with osteo-arthritic changes and partial ankylosis. He also states that the frequency of the attacks decreases with age. Joseph H. Pratt[3] quotes König's classification of the stages, which are: 1. Hæmarthrosis, effusion of blood into the joint. 2. Inflammation, with an addition of serum to the blood, a condition simulating acute tuberculosis. 3. Contraction, scar-formation, ankylosis. The fluid may be completely absorbed; the bone atrophies, but outgrowths are rare. Sir Anthony Bowlby, in his book, Surgical Pathology, states that the hæmorrhages lead to swelling, the clot sets up irritation, the cartilage fibrillates and becomes lipped at the margin as in osteo-arthritis, the synovial membrane is stained and fibrotic, adhesions are formed, but the bones and ligaments are unaffected. The following case illustrates several of these points.

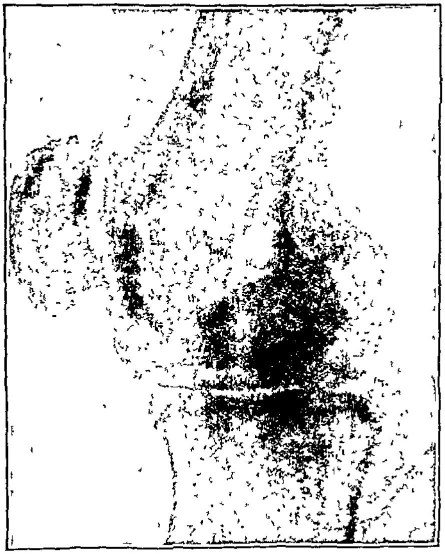
The patient, aged 32, was admitted to Westminster Hospital in December, 1913, suffering from acute arthritis of the right knee. He was very intelligent and gave the following history. He had been known to be a bleeder since the age of 2 years. No information was obtainable about his parents or grandparents; he had one brother and five sisters. His brother bled to death as a boy from a blow on the nose with a cricket bat. Two of his sisters are unmarried, three are married. Of the latter the first has two daughters, neither is a bleeder; the second has a son and daughter, the son is a bleeder; the third has a son and daughter, neither is a bleeder.

The patient had always bled readily from the nose and from wounds; he had been rather unfortunate in the frequency of the latter, and bore numerous scars. After a cut on the head on one occasion his whole head and face were swollen, with effusion into the eyelids. Apart from hæmophilia his health had been very good. At the age of 17 the left elbow became very painful and swollen after a slight injury, but recovered completely after two weeks in splints. He had had similar attacks in this elbow ever since, and after each there was increased limitation of movement. There had been similar attacks in the left wrist. At 18 the right elbow was affected, and he had attacks about every six weeks in this joint, on slight injury, sometimes if he only lay on the limb during sleep. At 19 the left knee was attacked after a fall from a scaffold, but recovered completely; a similar attack occurred the next year, also with recovery. At 22 the right knee was injured, and went black and blue; since then he had never been able to kneel, but for some years could walk without lameness. Four years later there was a similar attack in this joint after running; it was also the site of the attack for which he was last in hospital. The left ankle had frequently been swollen and transient swellings occurred in the hands, especially in one metacarpo-phalangeal joint. When an attack occurred the affected joint felt weak and stiff, after which burning pain came on which became very severe in five or six hours; sometimes the joint appeared bruised, and sometimes it became tightly distended "like an indiarubber ball." The swelling might subside very quickly, disappearing completely in two or three days, or it might persist indefinitely; the attack then under treatment had lasted six months.

---

[1] Treatise on Hæmophilia.
[2] Article, Hæmophilia, Allbutt and Rolleston's System of Medicine vol. v.
[3] Article, Hæmophilia, Osler's System of Medicine, vol. iv.

The present condition of the joints is as follows. The jaw, head, spine, and thorax were unaffected. Upper extremities: right shoulder unaffected; elbow flexes to 45°, extends to 135° (rough estimation); radio-ulnar supinates and pronates through about 135°; wrists and hands unaffected. Left shoulder unaffected; elbow flexes to 50°, extends to 150°; radio-ulnar supinates and pronates through about 110°; wrist, there is slight limitation in all directions; hands unaffected. Lower extremities: right hip unaffected; knee flexes to 35°, extends to 65° (see figure); ankle unaffected. Left hip and knee unaffected; ankle dorsiflexes to 90°, extends to 135°; foot unaffected.



From a skiagram taken with plate on inner side of knee, showing considerable change in surface of patella and condyle.

Blood examinations were made. The coagulation time by Wright's method was observed on four occasions by Dr. J. A. Braxton Hicks with the following results: 14 min., 60 min. 60 min., 30 min. (normal average 5 min.).

A skiagram of the right knee, taken by Mr. E. S. Worrall, shows absorption of cartilage and definite roughening of the articular surface of the femur.

Little can be done for such a condition, but the patient found that hot air baths and gentle massage gave comfort and increased suppleness. The manipulation of such joints is probably not without risk of renewed hæmorrhage, but none occurred in the present case. Hæmophilia is not a common condition, and the joint lesions are interesting as specimens of what is practically a condition of traumatic arthritis.

Wimpole street, W.

ON THREE CASES OF ECZEMATOUS DERMATITIS PRODUCED BY POISONOUS PLANTS.

BY ARTHUR WHITFIELD, M.D. LOND, F.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF THE SKIN, KING'S COLLEGE HOSPITAL.

MY reason for publishing the following cases is that I wish to draw attention once more to the great importance that attaches to the thorough working out of local causes in the production of so-called acute eczema. In THE LANCET of July 25th, 1908, I drew attention to a series of cases in which apparently eczematous eruptions were caused by local infection with a ringworm fungus; later Sabouraud worked out the variety and published his classical article on the subject. At the time that I published my series ringworm was, of course, well known, but was not suspected as a frequent cause of eczematoid eruptions on the hands and feet.

In the same way the cases to which I am now about to refer are such as are well known and have been frequently published where the sequence of handling the plant and developing the skin eruption has been so close as to call the attention of the patient, but in these cases this sequence was not so obvious, and in two out of the three cases the cause had not been suspected by medical men in charge. The point which I therefore wish to emphasise is that it is not enough to make the diagnosis of acute eczema, but that it is the duty of the specialist to make every effort to run to earth the cause of the eruption before contenting himself with local treatment and possibly the internal treatment of some hypothetical disorder of metabolism.

CASE 1.—The patient, aged 51, was sent to me with eczema of the face. The eruption had bothered her on and off for 13 months, and was said to have been started by kissing an old aunt who had a similar eruption The disease began round the alæ nasi and on the upper lip, but the red part of the lip was not affected This distribution made me suspect that it was not due to a dentifrice, which usually causes some dryness of the lip itself. During the year that she had suffered from the disease the patient had been abroad to different parts on two occasions, and on neither occasion had she suffered from the disease. When seen there was a condition of subacute eczema affecting the eyelids and the contiguous portions of the cheeks, so that the skin was reddened, stiffened with œdema, and had a tendency to crack. On inquiry it was found that the patient had a greenhouse in which she grew primula obconica, but she said that she had handled it for years with impunity. Nevertheless, as I had known of cases in which the susceptibility had been acquired, I suggested that she should banish the plants from her greenhouse The local treatment ordered was lead lotion with a very small amount of liq. picis carbonis added to it, and under this treatment the symptoms subsided at once and did not recur.

An interesting point about this patient is that a short time ago she wrote to me to tell me that her gardener suffered from an irritating eruption on the arms after moving some foxgloves and King Edward VII. daisies. I have looked up this latter plant in James White's classical monograph, and although he does not mention the chrysanthemum maximum he alludes to a single case due to the ox-eye daisy, leucanthemum vulgare, which is the parent of the chrysanthemum maximum.

CASE 2.—The wife of a medical man was brought to me for very acute eczema of the left eyelids and cheek only. The swelling was so intense that the eye was practically closed and the eyelids had the curious fawn-coloured translucency which is so familiar in acute eczema. The history showed that the disease began with a very sudden onset in June and attacked the right hand and arm, the left forearm, and the left eye. Shortly after the first attack she went to Ireland with her husband for a holiday, and although she bicycled a great deal in all weathers the skin remained perfectly sound. Twenty-four hours after her return home she had another attack, and five or six more attacks in the last three months before I saw her. There had been until the last attack an interval of freedom lasting nearly a month. Inquiry showed that she had primula obconica in her greenhouse for nearly a year, but in the last few days (i.e., just before the last attack) she had been given several more. The primulæ were all abolished and the disease disappeared.

CASE 3.—This case is of great interest, as the plant causing it is rare in this country. The patient, aged 56, was sent to me suffering from acute eczema of the face. When I saw her the attack was beginning to pass off, but the skin of the whole face was red, stiff with œdema, and showed slight fissures at the edges of the eyelids. The history showed that she had moved into a new house in May and had her first attack of eczema in June. She herself put it down to the trouble and work of moving coming on the top of the shock of a sudden family bereavement. She had no greenhouse and only a very small garden, and the only plants that she had were an aralia, some ferns, and aspidistras. After very careful inquiries on these points I then went to other possible sources of local poisoning and at one time thought it might be due to the use of a brass polish, but I found that she had not used any for a long period before the onset of the eruption. I then inquired about hobbies and found nothing there, and lastly thought of possible irritation from a green wallpaper. I had already arranged with her to send me some of this for analysis when she suddenly remembered a creeper on her house which she had forgotten to mention before. It was said to be like a Virginia creeper but was not one. I immediately asked whether it had three leaves or five and was delighted to hear that it had three. As the plant was deciduous and had no leaves at that time I knew I should be unable to identify it and advised that a piece should be sent to Kew Gardens for identification. The report came back, as I expected, that it was Rhus toxicodendron, or the "poison ivy of the United States," and the mystery of the eczema was thus explained.

Robinson in "The English Flower Garden" writes that some unprincipled nurserymen sent it out with a new name as Ampelopsis Hoggi and that it has been distributed in many gardens. Its poison is so virulent that cases of very severe illness and even death have been reported as due to it in America. It is probable that an American physician would have identified the case at once and would not have been three-quarters of an hour, as I was, before arriving at the correct conclusion, but the plant is so uncommon in this country that it was by great luck that I tracked it down.

In conclusion, I would remark that my object in publishing these cases is not so much to draw attention to the plant as a cause of dermatitis as to emphasise once more the importance of searching for an unsuspected local irritant. Eczema from dentifrices containing salol is common, and I have recently had three cases of eczema, two of which were due to photographic developer, and one, in a dental surgeon, was due to plaster-of-Paris. The number of these irritating materials is very great, and owing to the fact that only a small proportion of people are susceptible they are often overlooked.

Harley-street, W.

THE FATE OF A PLUG OF IODOFORM GAUZE ACCIDENTALLY LEFT IN THE ABDOMEN.

BY A. E. MAYLARD, M.B., B.S. LOND., F.R.F.P.S. GLASG.,
SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

A MARRIED woman, aged 33 years, was admitted to the Victoria Infirmary, Glasgow, under my care on May 10th, 1906, suffering from the presence of gall-stones. On the 16th she was operated upon, and 22 stones were removed from the gall-bladder and one impacted stone from the common duct. She left the infirmary quite well, and remained so for four years, until 1910, when she again suffered from symptoms of cholelithiasis. These attacks continuing, she was admitted for the second time, and a stone was removed from the ampulla of Vater. At the operation a long strip of iodoform gauze was conducted down to the sutured wound in the ampulla and led out of the parietal wound. The wound healed and the patient left the infirmary well.

A fortnight later, however, she began to be troubled with a "soreness in the right side and a feeling of fulness in the stomach." The symptoms which gradually developed were all suggestive of pyloric obstruction, and after admission to the infirmary there were succussion and well-marked gastric peristalsis. The inference was that the obstruction was due to adhesions, of which there was abundance encountered both at the first and still more at the second operation. The abdomen was opened with the object of performing the usual no-loop operation of posterior gastro-jejunostomy. On pulling up the first part of the jejunum for anastomosis with the stomach a most unusual condition of the bowel was found to exist. It was greatly increased in size, and the walls were greatly thickened and congested. An indefinite feeling of something within the canal was felt. The pyloric aperture was observed to be widely dilated, as also the first part of the duodenum. On opening the jejunum a foreign substance was at once seen which, when withdrawn, proved to be a piece of gauze about 15 inches in length. One part of the elongated mass passed up into the duodenum, while the other extended down the bowel. The upper end presented a large knob-like appearance somewhat whitish in colour and practically devoid of smell; the lower end was brownish in colour and fæcal in odour. The patient made a complete recovery and left the institution well.

The piece of iodoform gauze used at the second operation led down to the sutured incision in the ampulla of Vater. During the subsequent dressings of the case the question was once raised regarding the removal of the plug. Neither dressers nor nurses had seen it; and as no indication of its presence existed at the wound it was taken for granted that it must have been unknowingly drawn out during one of the removals of the outer dressings to which it had become adherent. The subsequent fate of the plug must have been that, *by pressure, it had ulcerated into the second portion* of the duodenum; and once admitted it had been gradually carried on through the normal peristalsis of the bowel. It seems somewhat strange that, having obtained complete admission, it was not carried on much further, even to the extent of being finally ejected per anum. However, although its removal was easy, it had led to impaction and partial obstruction of the canal.

The case is interesting as showing one way in which Nature is capable of successfully overcoming accidents of the kind, and doubtless had the plug been smaller it would have passed per anum and nobody have been any the wiser.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Specimens.—Three Cases of Cæsarean Section.—Uncontrollable Uterine Hæmorrhage.

A MEETING of this section was held on Feb. 5th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

Dr. HERBERT R. SPENCER showed a specimen of Fibroma of the Hymen, of the size of a pigeon's egg, removed from a married woman, aged 28, a virgo intacta. The tumour was a very cellular fibroma, and was ulcerated on the surface. It grew from the right half of the hymen, which formed its pedicle. Dr. Spencer knew of no record of such a case. The patient remained well after three and three-quarter years.—Remarks were made by Dr. T. G. STEVENS and Mr. CLIFFORD WHITE.

Dr. SPENCER also showed a Degenerated Myomatous Uterus resembling the pregnant organ, weighing 7¾ lb., removed by total abdominal hysterectomy from a virgin, aged 43. It closely resembled a pregnant uterus, which it was thought to be by experienced gynæcologists present at the operation. A section showing four myomata embedded in jelly, the result of degeneration, further increased the similarity. Dr. Spencer pointed out the value of bulging of the lower segment (which he believed never occurred in ordinary pregnancy), and of the absence of ballottement. True ballottement he had never met with in any tumour except the pregnant uterus, but if the jelly in this case had become liquefied it was possible that ballottement might have been obtained.—Remarks were made by the PRESIDENT, Dr. EARDLEY L. HOLLAND, Dr. H. WILLIAMSON, Dr. AMAND ROUTH, Dr. G. BLACKER, Dr. R. D. MAXWELL, and Professor H. BRIGGS.—Dr. SPENCER replied.

Dr. T. G. STEVENS read a short communication on Three Cases of Cæsarean Section. Case 1.—Cæsarean section; labour obstructed by one-half of a uterus diadelphys. The patient, aged 20, was admitted to Queen Charlotte's Hospital on account of obstructed labour due to a pelvic tumour. This was her second pregnancy, the first having terminated normally. On examination the head was found high up and the os three-quarters dilated. There was much œdema of the cervix. A soft tumour was felt behind the cervix bulging the posterior vaginal wall forwards below the head. It was thought to be an ovarian dermoid. It could not be pushed up. Cæsarean section was performed, and difficulty was experienced in releasing the fœtal head from the pelvic cavity. After closing the uterine incision in the ordinary way the tumour behind the uterus was investigated and found to be one-half of a double uterus with its Fallopian tube and round ligament complete. It was freely movable from the pregnant half. As the patient had already gone through one normal delivery it was decided to leave the double uterus alone. A complete decidual cast of the unimpregnated half of the uterus was passed on the third day. The patient did well. Case 2.—Eclampsia; vaginal Cæsarean section. This case occurred in a primigravida, aged 27, in the twenty-fourth week of pregnancy. A great many fits had occurred during the day before admission to Queen Charlotte's Hospital and during the following night. On admission the patient was quite unconscious. The urine was very scanty and loaded with albumin. The fundus uteri reached the level of the umbilicus. There were no uterine contractions, and per vaginam the cervix was long and rigid. Owing to her very serious condition rapid delivery seemed to be indicated, and vaginal Cæsarean section was performed (vaginal hysterotomy). The operation presented no difficulties, the cervix being closed by interrupted catgut sutures. The fœtus and placenta were delivered through the incision without any great trouble. The coma gradually lessened after the operation, and the patient could be *roused on the day following to drink fluids. On the third* morning after she was conscious and made a very good recovery. When examined on the fourteenth day the vaginal incision and the cervix had healed completely. Case 3.—Uterine fibroids, one impacted in the pelvis, obstructing delivery; Cæsarean hysterectomy. The case occurred in a patient who had been married five years; no previous pregnancy. She was first seen in March, 1913, and found to have a fibroid of the size of an orange low down on the posterior surface of the uterus and others at the fundus. The cervical fibroid could not be pushed above the brim. Pregnancy had practically been prevented during the five years of her married life. As she *seemed anxious to have a child, it was suggested that a* normal sexual life should be led, and she became pregnant soon after April 1st, 1913. In June the uterus was definitely enlarged, and although the cervical fibroid remained fixed it was decided to let the patient go to term and undergo Cæsarean section. This was done at the Mildmay Memorial Hospital on Jan. 8th. 1914, the uterus being eventrated to see if myomectomy was possible. It was then found that the uterus was very distorted, and that the supposed cervical tumour was really in the lower part of the uterine body, the whole expansion of pregnancy having occurred at the expense of the anterior uterine wall, the posterior being occupied by the large fibroid. There were other fibroids also. Multiple *myomectomy, together with Cæsarean section, seemed out of* the question, as it involved many incisions and much mutilation. Supravaginal Cæsarean hysterectomy was therefore performed. The case did well, except for troublesome distension and vomiting of large amounts of fluid, accompanied with collapse, which occurred on the eighth and twelfth days, due to dilatation of the stomach.—Remarks were made by the PRESIDENT, Professor BRIGGS, Dr. SPENCER, and Dr. J. D. BARRIS.—Dr. STEVENS replied.

Mr. GORDON LEY showed a specimen of Congenital Sacrococcygeal Tumour. The specimen had been removed by Mr. J. Preston Maxwell at the Hospital at Yung Chun, China, from the left buttock of a girl aged 16. It had existed since birth, and for 13 years sinuses, discharging sebaceous material, had existed in the gluteal cleft. The specimen consisted of a cyst, lined by skin, into which projected a well-formed hand with three fingers. The skin was covered by hair. In the wall of the cyst were bones, two of which resembled ribs. Accompanying the cyst was a piece of bowel opening on a skin-covered surface. In microscopical sections this resembled the recto-cutaneous junction. Mr. Ley demonstrated that the tumour was a teratoma; he stated that such a tumour might arise (1) from a primary germinal blastomere, (2) from a totipotential cell derived from post-primary blastomere. He pointed out that the inclusion of a twin save along the great longitudinal fissure was impossible, owing to the attachment of the amnion of the parent fœtus. Inasmuch, therefore, that the tumour in the case lay behind the rectum it could not be an included twin. He suggested that the tumour probably arose from an aberrant totipotential cell or from a totipotential cell at the posterior growing point. He was of opinion that the comparative frequency of sacro-coccygeal tumours made the latter hypothesis the more probable.

Professor BRIGGS and Dr. R. A. HENDRY (Liverpool) gave a report on 104 bleeding uteri after hysterectomy. The collection of uteri from the Gynæcological Laboratory of the University of Liverpool between April, 1901, and July, 1913, was arranged in three divisions—(1) 10, aged 28 to 35; (2) 81, aged 36 to 55 (delayed climacteric); (3) 13, aged 50 to 72 (post-climacteric hæmorrhage). *Tables were produced* —(1) of the position, weights, and measurements of the uterus; (2) of the hæmorrhage, its age incidence, its mode of onset, its puerperal relation, its duration, and its relation to the thickness of the endometrium ; (3) of parity ; and (4) of complications. The familiar effects of uterine hæmorrhage vary vastly from a grave secondary anæmia to an almost inappreciable invalidism or inconvenience ; the corresponding resourceful management recognises a small percentage of uncontrollable uterine hæmorrhage—clinically important and pathologically attractive to the investigator. A typical bleeding uterus was then described and shown to illustrate uncontrollable uterine hæmorrhage in the absence of an exercisable veto against "the uncontrollable"—a veto founded on the rarity of ultimate failure. Protraction of diagnosis and treatment forcibly promoted hysterectomy. Curettage was reviewed in its efficacy and failure in both exploration and treatment. In non-malignant cases the limiting line against repeated curettage must somehow be drawn. The total 40 local complications from the same or a dissimilar cause, distributed amongst 33 cases, left 71 uncomplicated cases in which the bleeding uterus reigned uninfluenced by collateral local disease. Dr. Hendry, as Ethel Boyce Fellow in Gynæcological Pathology during the past three years, had examined the 104 uteri—3 were sacrificed to mincing in unsuccessful searches for hæmolytic lipoids; 101 were submitted to a histological inquiry in reference to (*a*) the musculature, (*b*) the fibrous tissue, (*c*) the elastic tissue, (*d*) the blood-vessels, and (*e*) the evidences of infection. Under these headings the pathological report was presented in detail—18 post-mortem uteri were examined as controls. Sparse nucleation of the muscular bundles, consistent with hypertrophy or with subinvolution, fallible as evidence of muscular degeneration, was constant in the bleeding uteri before the climacteric. Variations in the fibrous and in the elastic tissues were identical in the bleeding uteri and the controls. With the solitary exception of calcification of the media in the uterus of a 17-para, the vascular changes were also identical in the bleeding uteri and the controls. Of the bleeding uteri four showed an acute infection ; and from 12 a chronic infection, either primary or secondary, could not be excluded. No abnormal histological changes could be found in the endometrium, and no relation could be traced between varieties of endometrium and the duration or severity of the bleeding. From the present available clinical and pathological evidence embodied in the report, the thesis was deducible that uncontrollable uterine hæmorrhage was a functional disturbance. The disturbers, local and general, were numerous and varied. Amongst them, arteriosclerosis, fibrosis uteri, chronic metritis, and chronic infective endometritis had been appraised too highly and too widely within the fields of gynæcological pathology and treatment.—Remarks were made by the PRESIDENT, Dr. WILLIAMSON, Dr. J. A. WILLETT, Dr. HENDRY, and Dr. HANDFIELD JONES.—Professor BRIGGS replied.

SECTION OF ANÆSTHETICS.

Intratracheal Anæsthesia.

A MEETING of this section was held on Feb. 6th, Dr. J. BLUMFELD, the President, being in the chair.

Mr. ROBERT E. KELLY read a paper on Intratracheal Anæsthesia. He said that the intratracheal method was an artificial respiratory method first, and an anæsthetisation method secondarily, and that obstructed respiration, the only danger in ether anæsthesia in a large percentage of cases, was absolutely eliminated. After dealing with the physiology of respiration he said that life could be maintained without respiratory movements by forcing air down the trachea, as shown by Meltzer and Auer, and that this had been tried in cases of poisoning when the respiratory centre had been paralysed. In reference to thoracic surgery this method was a great improvement on the "positive and negative" pressure cabinets. In the latter the disadvantages were that the thorax and head were in different atmospheres, and also asepsis became difficult. By this method work had been done in the American experimental laboratories on the heart, lungs, and great vessels in animals. The anæsthetist was entirely out of the way ; blood, pus, and vomited matter were not inspired, and extreme accuracy of dosage could be maintained. Owing to the lessened respiratory movements manipulations in the upper part of the abdomen were facilitated. In nearly 300 cases vomiting and sore-throats from passage of the catheter were rare, and no fatalities had occurred.

Mr. H. E. G. BOYLE said that he did not consider th method suitable or advisable for all cases. The anæsthetis should make himself familiar and skilled in every know method of anæsthesia, and should be given an opportunity o seeing every case beforehand, so as to be able to decide wha method was most suitable for patient and surgeon. He said tha it was pre-eminently suitable for intrathoracic surgery, an mentioned a case of pyopneumothorax in which abou 3 ounces of pus had been blown out of the trachea. I cases of goitre the surgeon could pull on the growth wit impunity, although care must be taken not to kink th trachea. If required, the patient could easily be brough round sufficiently to cough before completion of the operation. A mixture of oxygen and ether could also b substituted for air-laden ether. It was a satisfactory metho for cleft palate, removal of upper jaw, and operations in th neck. In an operation for removal of tongue and glands through the mouth and neck, and in which a ligature of a big vein had slipped, the patient had only been saved from being drowned by his own blood by the presence of the intratracheal catheter, which kept the trachea free. Mr. Boyle considered the introduction of the catheter the most difficult part of the method.

Dr. F. E. SHIPWAY agreed with Mr. Kelly that the method was essentially one of artificial respiration. Among the advantages a free air-way was always present, and cyanosis could not arise ; the administration was even and constant; the power of excluding blood, &c., from the larynx and lungs; the field of operation in head and neck operations could be kept sterile. In abdominal operations relaxation was very good and respiratory movement slight, and shock was also diminished. He was strongly of the opinion that the vapour administered by this method should be warmed to body heat.

Dr. M. S. PEMBREY spoke of physiological observations upon intratracheal anæsthesia, made in conjunction with Dr. Shipway and Dr. G. Marshall, who had investigated the blood pressure. The rate of ventilation had averaged about 16 litres per minute and extremes varied from 8 to 30 litres per minute. A rate of 30 litres or more produced apnœa, but this was inadvisable. Respiratory movements showed that the pressure was not too great for the anæsthetised muscles. The ease with which a light anæsthesia could be maintained was the outstanding merit of the method.

Dr. GEOFFREY MARSHALL said that he had taken records of blood pressure during anæsthesia by this method. A Riva-Rocci apparatus was used on the brachial artery. Compared with other methods of anæsthesia, it was striking that there was very slight fall of blood pressure during a long operation. During the operation the blood pressure varied 5–10 mm. mercury about the mean pressure. Blood pressure was found to vary directly with the CO_2 tension.

Dr. WILLIAM HILL considered that insufflation of anæsthetics under pressure was inadvisable except in thoracotomic operations. For goitres, for instance, oro-tracheal intubation with a funnel or Junker's apparatus was all that was needed. He used this method for œsophageal work, and in other operations where there was tendency to obstruction of the trachea. To prevent blood, &c., entering the air passages he used a thin wide rubber collar attached to the oro-tracheal catheter, and which rested on the ventricular bands. Dr. Hill showed patterns of laryngoscopes and the method of introducing the catheters was demonstrated on a patient under cocaine.

Dr. G. A. H. BARTON thought that the endotracheal method had only a limited application and that for ordinary cases it offered no advantages. The sole difficulty lay in the introduction of the tube. In regard to the air pumped from the floor by foot-bellows, he doubted whether this could be considered as sterilised in its rapid passage over the ether.

Mr. T. B. LAYTON said that he had had experience of the method and for throat and nose operations had liked it very much. The great advantage was that there was no need to stop to mop up every trickle of blood that passed to the back of the mouth.

Dr. W. J. MCCARDIE said that the weak point of the method was the depth of anæsthesia necessary to introduce the catheter, and which was frequently not safe in cases of goitre and intestinal obstruction.

Mr. KELLY replied.

SECTION OF OPHTHALMOLOGY.

Sympathetic Ophthalmia.—The Use of Salvarsan in Ophthalmic Practice.

The adjourned meeting of this section was held on Feb. 16th for the purpose of concluding the discussion on the Use of Salvarsan in Ophthalmic Practice.[1] The chair was occupied by Sir Anderson Critchett, the President.

Mr. W. Lang showed a case which, in 1908, developed Sympathetic Ophthalmia following a gunshot wound, contrary to the general belief that sympathetic trouble did not follow injury. Much benefit had occurred from giving salvarsan.—Mr. J. H. Parsons, discussing the case, thought it showed that sympathtic ophthalmitis was a general infection, and it would be difficult to believe that a purely local condition could persist for three years, the interval between the injury in this case and the subsidence of the sympathetic trouble.—Mr. J. H. Fisher also spoke of two cases in which Mr. S. H. Browning forecast the onset of sympathetic trouble from the blood count.

Lieutenant-Colonel R. H. Elliot, I.M.S., continued the debate on the Use of Salvarsan. He said that he had had no experience with neosalvarsan. As he had had an experience [illegible] reported, and he believed the reason was that they did not occur; they were able men and fully on their guard. On the other hand, it was their experience that those cases which presented signs of optic neuritis, of presumably syphilitic origin, acted excellently to the remedy. As the whole of a dose of salvarsan seemed to be eliminated from the system in ten days, he thought any trouble which was likely to arise would be evident in a month or so, after which period no anxiety need be felt. In his large practice in Madras, the intramuscular method was abandoned in favour of the intravenous, largely on account of the pain caused by the former, which in many cases necessitated the use of morphia. A Wassermann test was done in each case, and the administration was not continued after that was negative. In no case did they abandon mercury and iodide, which were given in the intervals. The most startling benefits were obtained in recent or acute cases involving the uveal tract. One man was practically blind, with a congested eye, his vitreous was full of opacities, and a gummatous mass involved the ciliary body, yet within a week of using the remedy he could count fingers at a distance of from 20 to 30 feet. His general nutrition also improved. With muscle palsies and optic neuritis the results were very satisfactory, though not with tabetic conditions. He knew of two deaths following the use of salvarsan, both in marasmic patients, who probably would not have lived long in any case. With regard to sympathetic ophthalmitis, Gifford, of Omaha, from the results obtained in it from atoxyl and salvarsan, argued that it was a general protozoal disease.

Mr. E. E. Henderson narrated two cases, one a patient, aged 72, in whom "606" produced excellent results in sympathetic ophthalmia, though the condition was very severe.

Dr. Alexander Fleming said that when salvarsan was introduced into this country it was said to have ruined many eyes, but there seemed no real evidence that the drug had produced an evil effect on any eye; not any cases of optic nerve trouble had followed its use at St. Mary's Hospital. He preferred salvarsan to neosalvarsan, though the latter was very easy to use. He had never seen much benefit from salvarsan in interstitial keratitis. In one case a chancre of the inner canthus disappeared in a few days under the treatment. In choroiditis the results were very rapid and complete. In one case an Argyll-Robertson pupil, in a case diagnosed by a physician as tabes, became a normal pupil under the treatment.

Major W. S. Harrison, R.A.M.C., thought that the timidity felt about using salvarsan was largely due to the evil repute of atoxyl and soamin, but there could be no doubt about the beneficial effects of salvarsan. He had seen a case in which omission to use salvarsan on account of its supposed neurotrophic effect on cerebral nerves resulted in a calamity. He proceeded to discuss points in the technique, and expressed the opinion that as all the salvarsan given could not be collected in the urine, probably the drug was not entirely eliminated from the system as soon as was supposed. Still, by spacing out the doses at intervals of not less than a fortnight, any cumulative effect need not be feared. If a case seemed to indicate more frequent doses, he thought there would be little danger. He had not had any catastrophes in his practice with salvarsan.

Mr. J. B. Lawford read notes of a severe case of post-operative plastic iritis treated by neosalvarsan, the patient being a man aged 60, the subject of acute gout. The operation was extraction and iridectomy. There followed hazy cornea, ciliary injection, exudation, and the formation of a hypopyon. A mixed staphylococcus vaccine produced no visible effect. Nineteen days after the extraction 0·9 grm. of neosalvarsan was injected intravenously, and in two days there was definite improvement, while four days later the hypopyon was very small and the congestion was diminishing. The patient went home, but returned later, and the hypopyon had recurred. A similar dose of neosalvarsan was injected, and almost immediately the eye became brighter, and there was general marked improvement.

Mr. S. H. Browning, in answer to a number of questions, admitted that the blood count by which one could forecast the onset of sympathetic trouble was not infallible, but it was true in the great proportion of cases. The discovery of this particular blood count did not mean that the eye would be inevitably excised; efforts to save the eye would be persisted in as long as they were of any avail.

Mr. Basil T. Lang pointed out that many of these cases of injury of the ciliary region occurred in children, and it should be remembered that the total number of leucocytes in the blood varied from the moment of birth until after puberty. Until the second or third year of age 80 per cent. of the blood cells present were of the lymphocyte type—i.e., large mononuclears, large lymphocytes, and small lymphocytes. Therefore, finding a child with such a blood count must not be taken to mean that it was on the eve of sympathetic ophthalmia. He believed salvarsan to be a very good tonic from his observation on cases.

SECTION OF PATHOLOGY.

The Pathological Changes of the Thyroid in Disease.—Channels of Spread in Bacterial Infection.—Changes in Malignant Tumours on Exposure to the Gamma Rays of Radium.

A meeting of this section was held on Feb. 17th, Dr. F. W. Andrewes, the President, being in the chair.

Mr. Rupert Farrant read a paper on the Pathological Changes of the Thyroid in Disease, a summarised version of which will be printed in The Lancet later.

Dr. F. H. Thiele read a paper on the work carried out by Dr. D. Embleton and himself on the Channels of Spread in Bacterial Infection. The authors showed that the urethral mucous membrane was very permeable to bacteria and that the organisms reached the heart's blood and underwent general dissemination within two hours after painting them on the mucous membrane. The channel of spread was by way of peri-ureteral lymphatics to the capsular lymphatics of the kidney to the thoracic duct. It was shown that the covering of the glans penis was not so permeable to bacteria as the urethral mucous membrane. This rapid passage of bacteria to the heart's blood after absorption from the urethra might account for catheter fever. The vaginal mucous membrane is not permeable to bacteria. The conjunctiva was similarly found not to be permeable. It was shown that by feeding animals with bacteria infection could occur through the normal buccal mucous membrane, and that the channel of spread was by the lymphatics to the salivary glands, the lymphatic glands in connexion with them, and the cervical glands, the further spread depending upon the nature and virulence of the organism. The authors were unable to confirm the work of Calmette, Whitla, and Symmers. They found that the lungs did not act by any means as efficient filters, keeping back bacteria reaching them by way of the thoracic duct to the right heart, but that bacteria, once having reached the thoracic duct, underwent general dissemination in the body. Intestinal infection is relatively difficult. In ordinary feeding experiments alimentary infection appeared to occur chiefly through the buccal [illegible] Bacteria and particulate of the serous cavities were entirely absorbed along the lymphatics, and in the case of the peritoneum, if the thoracic duct were opened the organisms were prevented from gaining access to the blood and organs. The absorption and passage along the lymphatic channels is extremely rapid, since organisms were demonstrated in the blood, within two minutes after intraperitoneal inoculation. It was also shown that diffusible substances were absorbed both by the lymphatics and blood channels; by the former more than the latter. In serous cavity infections spread also occurred along the lymphatic channels leading to the mediastinal glands, but this was relatively slight and unimportant. It was demonstrated that in addition to easy communication between the subarachnoid space and the venous sinuses there was a very free communication with the thoracic duct. Organisms appeared in the thoracic duct within five minutes after inoculation into the subarachnoid space. From the experiments it did not appear that there was any free circulation of cerebro-spinal fluid in the brain substance, since the inoculation of pigments, dyes, and bacteria into the cerebro-spinal fluid or intraventricularly was not followed by any spread into the brain substance along any of the perivascular subarachnoid sleeves. The experiments threw no light on the presence of an intracerebral lymphatic system, since pigment and bacteria inoculated in this way remained absolutely localised, and could not be demonstrated in the cerebro-spinal fluid, lymphatic channels, or tissues. It was also observed that bacteria and pigment could travel along the perineural lymphatics of the peripheral nerves, but the spread never occurred to the cerebro-spinal fluid or cord. Diffusible substances, however, travel along the axis cylinder fairly rapidly, and could be traced along the nerve roots. The authors concluded: 1. That bacterial spread is primarily by way of the lymphatics, the bacteria rapidly passing to the thoracic duct and blood stream and rapidly undergoing general dissemination. 2. That bacteria do not have specific sites of predilection peculiar to themselves. With every infection after bacteria have gained access to the thoracic duct a general dissemination occurs, and if looked for at the proper time the bacteria can be found in every tissue, the sites in which they can ultimately be found depending on the rate at which they are destroyed in that organ. 3. The lungs do not act as efficient filters. 4. Whenever bacteria occur in the blood they are excreted in the urine, and there is no need to suppose an increased permeability of the kidney for this purpose. 5. Bacteria cannot pass from the lymphatics into the urine. The capsular lymphatics of the kidney may be full of bacteria, but they only get into the urine after they have gained access to the blood. 6. Even when general bacterial dissemination occurs the serous cavities remain free from infection for a very long time.

---

[1] The Lancet, Feb. 14th, 1914, p. 459.

Mr. A. Clifford Morson read a paper on the Changes which occur in Malignant Tumours on Exposure to the Gamma Rays of Radium. He found that the effects of these rays on malignant cells were two-fold—(*a*) rapid degeneration of the malignant cells in the immediate vicinity of the tube of radium; (*b*) apparent vacuolation and enlargement of nuclei in cells beyond the degeneration zone. He pointed out that considerable difficulty arose when an attempt was made to interpret the meaning of the changes, because Wedd and S. Russ had exposed mouse carcinoma to the beta rays, outside the body, for periods varying from one hour to 24 hours and failed to find any microscopic changes, unless the irradiated tumours were reinoculated. These observations suggested that the change produced in the cancer cell was a chemical one, and it was only when in contact with certain living constituents of the body that these degenerative changes could be brought about. He was of opinion that a knowledge of the degree of sensibility of different types of malignant cells on exposure to the gamma rays was the keystone to improvement of treatment of cancer with radium. As determined by the rapidity of onset of degeneration he had found that the cells of those tumours which by ordinary methods of histological diagnosis appear to be round-cell sarcoma are very sensitive to the action of radium. In the carcinomata there were remarkable differences in sensibility. He then made a few cautious remarks upon the question of changes in metastases. In the case of secondary deposits in lymphatic glands, though the material at his disposal had been limited to four cases, he had observed macroscopic and microscopic changes of a regressive type which called for further investigations. He considered it possible that the absorption of degenerated and degenerating cancer cells at the primary site due to exposure to the gamma rays might lead to the formation of some substance which would retard the growth of the malignant cell.

SECTION OF OTOLOGY.

Exhibition of Cases.

A meeting of this section was held on Feb. 20th, under the presidency of Mr. Richard Lake.

Mr. C. E. West related a prolonged and critical case of Chronic Suppurative Otitis Media in a child, aged 5, in whom five operations eventuated in recovery. There was a long history of discharge from both ears, then cessation, followed by renewal on the right side. There were, for the week preceding admission, headache, vomiting, and increasing drowsiness. There were no local signs over the mastoid or in the neck. The pulse was irregular, rate 68; temperature 97 8° F.; respirations 20; slight lateral nystagmus on deviation of eyes to the right. At the radical mastoid operation cholesteatoma and extradural suppuration were found; also a sinus leading to the interior of the cerebellum and 2 drachms of foul pus were evacuated. Cultures and films gave pure streptococci. On doing lumbar puncture the fluid was sterile; 650 cells per cmm., 93 per cent. lymphocytes. Eight days later the pulse fell to 62, and a second operation was needed, when a drachm of pus was removed. Owing to reaccumulation bone was removed from the outer side of the sinus, and a fresh collection of pus in the cerebellum was drained by a deeply inserted tube. The patient was much worse on the following day; pulse 60, respirations less than 10 per minute. Three weeks after the first operation Mr. West widely removed the tabular part of the occipital bone and underlying dura mater, and the region of the abscess was thoroughly exposed, the brain tissue being largely necrotic. There were weakness and wasting of the right limbs. Two months later the hernia cerebri was dealt with, a large flap of scalp and periosteum being slung downwards to cover the hernia, and the bared bone was grafted. Great shock followed, but it was recovered from after the use of pituitrin and intravenous saline. The health of the patient during the last 12 months had been satisfactory and the hernia had diminished and become firmer.—The case was discussed by Mr. F. F. Muecke, Dr. F. H. Westmacott, and Mr. Sydney R. Scott.

Dr. H. J. Davis showed a case which was affected with Herpes Zoster of the auricle. The case was sent as one of acute mastoid disease, owing to the great pain which preceded the eruption.

Mr. W. M. Mollison demonstrated by means of a section that infection could spread through a small vessel in the temporal bone and become generalised, the patient succumbing to this. Post-mortem examination revealed secondary abscesses in the lungs. He also showed a case of Tumour of the Left Cerebello-pontine Angle. There were nystagmus and defect of vision, especially in the left eye, which reacted only feebly to light. Papillœdema existed on both sides, particularly the left.

Dr. W. H. Kelson exhibited a man, aged 43, in whom Ménière's symptoms had been relieved for three months by the operation of uncapping the external semicircular canal.

MEDICAL SOCIETY OF LONDON.

Exhibition of Clinical Cases and Pathological Specimens.

A meeting of this society was held on Feb. 23rd, Sir David Ferrier, the President, being in the chair.

Dr. J. Porter Parkinson showed a case of Syphilitic Cirrhosis of the Liver. The patient was a woman who was first seen in 1909 with a history of abdominal swelling of four months' duration and bilious attacks. There had been no hæmatemesis or vomiting. At that time the liver and spleen were both enormously enlarged, reaching on each side well below the anterior superior iliac spines. There was no ascites. The white corpuscles numbered 4600 per cubic millimetre, the proportions of the varieties being normal. She had been re-admitted a month ago for ascites. She was rather wasted, with a browny yellow skin, but no conjunctival jaundice and no bile in the urine. The liver and spleen had shrunk considerably, and the former was distorted and converted into irregular masses in a manner strongly suggestive of syphilis. Twelve pints of ordinary ascitic fluid was drawn off in January, but it refilled, and about one month later 16 pints were removed. The blood count on Feb. 13th showed red corpuscles, 2,030,000; white cells, 3000; polynuclears, 68 per cent.; lymphocytes, 32 per cent. Some poikilocytes were present, but no nucleated reds were seen. No megaloblasts were present. The Wassermann reaction was at first negative, but as there was some doubt as to its accuracy it was again tried and was positive. There was no direct history of syphilis.

Dr. Parkinson also showed a case of Patent Ductus Arteriosus. The patient was a girl, aged 6 years, with a history of phthisis on the father's side. She was admitted to hospital for slight bronchitis. She was a fairly well grown child, not cyanotic, but slightly dyspnœic on exertion. The cardiac impulse was in the fifth space, 1½ inches outside the nipple line, slightly heaving in character. The right limit of the deep cardiac dulness was 1 inch to the right of the sternum; the upper limit reached to the upper border of the second rib cartilage (Gerhardt's area of dulness). There was a systolic thrill in the second left intercostal space, and a loud murmur extending over nearly the whole of the cardiac cycle, best heard in the second left intercostal space, but heard over the whole cardiac area, not well conducted to the back. The pulmonary second sound was loud and often reduplicated. The other viscera appeared to be normal, and there was no other malformation. A radiogram showed the enlargement of the heart and the shadow due to the pulmonary artery.

Dr. C. E. Lakin showed the organs from a case of Hæmochromatosis with Primary Carcinoma of the Liver. The patient was under the care of Dr. W. Essex Wynter, to whom Dr. Lakin was indebted for permission to show the specimens. He was a male, aged 68. For three months before admission he complained of indigestion, and for the last month of shortness of breath, enlargement of the abdomen, pain in the right leg, loss of weight, and vomiting of blood. Post mortem, there was slight bile staining of the conjunctivæ but no jaundice of the skin. An enlarged gland (Virchow's) was found in the left supraclavicular fossa. Slight pigmentation of the skin of the legs was present. The aorta was atheromatous. There was a slight degree of mitral stenosis. The heart muscle was dark brown in colour. The lymphatic glands in all the regions examined were of an intense brown colour, and secondary deposits where they were present in the glands contrasted markedly with the brown gland substance. Microscopically while the glands showed well marked Prussian blue reaction the new growth, which was a spheroidal celled carcinoma, appeared to be entirely devoid of iron granules. The pancreas was salmon brown in colour. The liver showed the characteristic brown tint and gave a well marked Prussian blue reaction. The spleen showed perisplenitis. Microscopically these organs showed quantities of hæmosiderin but little evidence of fibrosis, which might account for the absence of sugar in the urine. The percentages of iron estimated by Dr. Kellas for the different organs were: liver, 2.47 per cent.; pancreas, 0.48 per cent.; and lymph glands, 7.32 per cent.

Dr. Edmund Cautley and Mr. N. Bishop Harman showed a specimen of Syphiloma of the Heart. According to the father the patient lost her mother from "cancer of the heart." There was no history of congenital or acquired syphilis. The girl had had excellent health, except for chorea in childhood and occasional sore throats. At the beginning of May, 1912, she developed keratitis profunda in the left eye. There was ciliary injection and a streak of fine precipitates on the back of the cornea. The iris was normal. No vitreous opacities or choroiditis could be found. The vision was 6/12, not improved by glasses. The right eye was normal with vision 6/6. The girl was carefully examined for some septic focus, but none was found, and all the organs except the eye were apparently normal. The teeth were of good shape and condition. Under atropine ointment and boric acid fomentations she recovered completely in about a month. The girl continued her duties, and never suffered from shortness of breath or signs of ill health until November, when she was found dead. The heart weighed 17 ounces. The wall of the right ventricle and the interventricular septum were extensively infiltrated with hard fibrous new tissue somewhat nodular. Dr. Stanley Wyard reported that the microscopical appearances were those of gumma. The case was unusual by reason of the patient's age, the complete absence of symptoms, and the limitation of the disease to the cardiac muscle.

Dr. W. H. Willcox showed a case of Tumour in the region of the Sella Turcica. The patient was a married woman with several children. There had been no miscarriages. Menopause occurred at the age of 39. She was in good health until March, 1913, then complaining of attacks of violent abdominal pain. Her medical attendant told her she was jaundiced. She was treated for gall stones and suffered from abdominal pain on and off, this symptom gradually becoming more severe. On July 23rd the patient became much worse and vomited continually. There was some diarrhœa. She complained first on that day of being unable to see properly and was drowsy and disinclined to talk. On July 24th there was no vomiting, but the patient was no better. On July 25th she complained of severe frontal pain and on July 26th became delirious. She still recognised her parents, but her sight was very much impaired. She was admitted to St. Mary's Hospital on the evening of July 26th, 1913. On admission she was completely comatose, with stertorous breathing and some cyanosis. The temperature was 102.5° F., pulse 100, and respirations 24. There was incontinence of urine. Ptosis of the right eyelid and some facial weakness on the right side were present. The pupils were unequal, the left being larger than the right. Both pupils reacted to light. The knee jerks were absent. There was an extensor plantar reflex present on each side. The tongue was furred and the breath foul. The heart and lungs were normal. The abdomen was distended. The liver and spleen were normal. Retention of urine occurred later and the urine had to be regularly drawn off by a catheter. The urine was acid, its specific gravity 1026. Urea 3.9 per cent. A faint trace of albumin was present. No acetone or diacetic acid was present. The patient remained comatose until July 30th. On this day she was able to speak and complained of being unable to see. The eyes were examined but no optic neuritis was observed, the discs being pale and the vessels small. Ptosis of the right eyelid was very marked. On July 31st she was more conscious and the ptosis of the right eye was less marked. There was definite weakness of the right arm and also of the right side of the face. There was complete ophthalmoplegia of the right eye and she could not see at all with either eye. Some impairment of outward and upward movements of the left eye was present. The temperature became normal on August 3rd. The patient remained in an abnormal mental state and on August 14th she had delusions that her husband and children were present and that someone was trying to poison her. On August 18th her mental condition became normal. The ptosis gradually cleared up and the right eye gradually recovered its movements. On August 11th she was able to see slightly, but could not recognise objects. The weakness of the right arm and face cleared up. She left hospital on Sept. 23rd. She was able to recognise hand movements, but vision was very indistinct. The ocular movements were normal except that there was some deficiency of outward movement of the right eye. The ptosis of the right eye had gone and the mental condition was normal. A Wassermann test gave a positive result on July 30th. She was treated with inunction of mercurial ointment and subcutaneous injections of soziodol of mercury. Iodide of potassium was given by the mouth. She developed some stomatitis on August 10th, and the mercury was stopped for a few days. She attended the out-patient department of St. Mary's Hospital on Jan. 1st, 1914, and then had Argyll Robertson pupils and well marked bitemporal hemianopia. Her ocular movements were normal. Her general condition of health was good. An X ray photograph by Dr. G. Harrison Orton showed marked enlargement of the sella turcica. Mercury and iodide had been continued during the past four months. She had on Jan. 28th a fresh attack of abdominal pain lasting two days.

Dr. W. Essex Wynter showed a case of Femoral Drainage for Ascites in Advanced Cirrhosis. The patient, a woman, was admitted in September, 1912, with ascites. The abdomen was very tense and there was much respiratory distress. Paracentesis was performed on Sept. 16th, 9 pints of serum being removed. By Oct. 17th the abdomen was again tense and an attempt was made, by placing a decalcified bone tube in the peritoneal cavity, to drain into the subcutaneous tissue of the lower thoracic region. Suppuration occurred in the integument and the bone tube was discharged, but the fluid remained in abeyance till Dec. 17th. There was then a rapid accumulation and on Jan. 5th, 1913, 11 pints were removed by tapping. She was discharged on Jan. 8th. She was readmitted on Jan. 22nd, and being very tense was tapped at once, but not satisfactorily. On Jan. 24th the femoral ring was opened with the aid of a cannula and probe passed through the abdominal wall above, a decalcified bone tube was inserted, and the wound closely sutured, about five pints of fluid escaping. During convalescence there was some œdema about the wound and a few drops of sanious fluid escaped, but the abdomen became smaller, and the patient recovered her strength. By Feb. 2nd she was convalescent except for a continued temperature of 100° F., due to some tuberculous trouble at the right apex, and dry pleurisy over the left front. *She was discharged on March 22nd and there had been no* occasion to tap the abdomen since. The higher operation was undertaken as a compromise, as at first the patient appeared too ill to stand the more complete femoral incision or repeated tapping. Incidentally, it afforded an opportunity for ocular demonstration of the cirrhotic liver. Sufficient improvement in the general condition followed to permit of the more radical operation, and the ultimate result had been quite satisfactory in spite of the advanced stage of cirrhosis evident in the observed state of the liver and the obvious aspect. Ascites was present, but the need for repeated tapping was obviated.

Dr. R. A. YOUNG showed a case of Acquired Double Mitral Disease in a Transposed Heart. The patient was a girl aged 10 years and 10 months. She had suffered from rheumatic fever three years ago followed by chorea, and came under observation for a cough of ten weeks' duration and headache. The cardiac impulse was in the right axilla, and cardiac dulness to the right of sternum. A sharp first sound and systolic murmur were audible at the situation of the impulse. X rays confirmed the diagnosis, and aided by a bismuth bolus showed that the stomach was on the right side.

Dr. E. A. COCKAYNE showed a specimen of Rheumatic Nodules on the Heart.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Exhibition of Clinical Cases.

A MEETING of this society was held in the board room of the Great Northern Central Hospital on Feb. 12th, Dr. T. WILSON PARRY, the President, being in the chair.

Dr. ALEXANDER MORISON showed a girl, 11 years of age, who had had Epilepsy since she was 2 years old. The attacks were at times of very frequent occurrence, as many as 38 occurring in 24 hours. While under his care they were characterised by clonic convulsions affecting the right half of the body. At a former period (1909) they were stated to have affected the left side. Finding the bromides ineffectual in arresting the attacks, Dr. Morison used hypodermic injections of sulphate of atropine (1/200 gr.) three times a day with immediate diminution of the frequency of the attacks and in a few days in their disappearance, when the atropine was administered by the mouth ultimately in doses of 1/100 gr. twice a day. With the abandonment of the drug there was a tendency to recurrence of the attacks and at its resumption they disappeared for lengthened periods, only supervening occasionally as a single attack. While recognising this clinical fact that there are spontaneous periods of cessation of attacks in epilepsy, Dr. Morison felt inclined to regard atropine as having had a beneficial effect in this case and as affording some support to the vaso-motor theory of the origin of the attacks, at any rate in some cases of epilepsy.

Dr. E. BELLINGHAM SMITH showed two cases of Aphasia. The first was a case of Jacksonian Epilepsy—Right Hemianopia and Word Blindness. The patient was a man who had contracted syphilis 28 years ago, and was now being treated for convulsive movements affecting the right side of the face and right arm, and also for difficulty in reading. The illness commenced in February, 1912, with an attack in which the patient suffered from sudden loss of sight in the right eye and loss of speech and numbness in the right arm. Since that date the patient had had attacks, recurring every two or three weeks, of convulsive movements of the right side of the face and right arm; these attacks were preceded by a "burning sensation" in the right eye, and were not associated with any loss of consciousness. He complained that his sight was very imperfect in his right eye, and that to obtain a clear view of objects he must turn his head to the right. In addition he had difficulty in reading. He said that he could see the print, but had difficulty in understanding what he read. On examination it was found that he recognised and named objects correctly, that he read very slowly and aloud, spelling each letter deliberately; he could then enunciate short words but stumbled over or completely fell at long ones. The difficulty with some letters was greater than with others. He wrote from dictation and copied quite well though slowly. When writing from dictation he repeated the words *to himself. If, however, he was shown what he had written* he again had difficulty in reading it. Except for a considerable degree of contraction of his right field of vision he was free from any other evidence of nervous disease. These symptoms suggested that this man was suffering from a gummatous meningitis, giving rise to epileptiform convulsions of the Jacksonian type, while the hemianopia and word-blindness without agraphia could be explained on the assumption that he had some syphilitic obliteration of the vessels supplying the general visual centre in the occipital lobe and the region of the association fibres connecting the general visual centre with the word-memory centre and the angular gyrus.—Dr. HARRY CAMPBELL was inclined to accept Dr. Bellingham Smith's explanation of the case—namely, that the visual and aphasic phenomena were due to softening from endarteritis, and that the minor Jacksonian attacks were caused by a localised meningitis or actual gumma. He held that all cases of cerebral syphilis should be treated without delay by the intravenous administration of salvarsan, in conjunction with mercury. If this failed recourse should be had to the intrathecal injection of salvarsanised serum. He incidentally referred to the good results he had obtained from this method of treatment in tabes. He urged that in prescribing potassium iodide for syphilis of the central nervous system not less than drachm doses, three or four times a day, should be ordered.

Dr. BELLINGHAM SMITH'S second case was one of Motor Aphasia and Partial Hemiplegia. The patient was a female aged 24. Nine weeks ago she was confined. The confinement was attended by a considerable loss of blood, which left the patient, in her own words, "very weak and breathless." Three weeks after the birth, while the patient was sitting at dinner, she felt a sudden numb feeling in the right arm and found that both her right arm and the right side of her face were paralysed. On attempting to speak she was unable to utter a sound. Complete aphasia lasted for three days; since then her speech had been slowly and steadily recovering *pari passu* with her paralysis of arm and face. On examination it will be noticed that there is a slight weakness of the right side of the face, which is more marked on smiling. The movements of the right arm appear normal, but the finer movements of the fingers, as required for threading a needle or writing, are still very deficient. As regards her speech, she hears well and understands what is said to her; she can also read readily and understands what she reads. She, however, says that when she wants to speak or reply "she knows what she wants to say but can't get it out without hesitating, stammering, clipping her words, or even occasionally using an entirely wrong expression." She can write so far as her paralysis admits, but is incapable of counting money. In this instance the inability to count, the difficulty in expressing herself, and the use of wrong words, associated with her previous history of loss of blood and resulting anæmia, suggest that this patient is suffering from some cerebral thrombosis which has temporarily disorganised her motor areas subserving the movements of face and hand and also the kinæsthetic memory *centre*, which controls intelligible speech.

Dr. H. L. TIDY showed a case of Tuberculide of the Hands combined with Bazin's Disease. The patient was a girl aged 20. Eighteen m[illegible] hands, which have per[illegible] ache on exertion, but [illegible] a nodule will rupture and discharge slightly. About three months ago she noticed a few lumps under the skin above the right ankle, several of which have formed ulcers. On both hands are numerous cutaneous nodules, about the size of a sixpence, of bluish tint and very slightly indurated. The circulation is good. On the right calf are several ulcers of the same size with blue peripheries, and subcutaneous nodules can be felt. On the left calf are a few subcutaneous nodules. In both posterior triangles of the neck are numerous small discrete glands. Otherwise there is nothing abnormal to be found.

Mr. GORDON TAYLOR showed a case of Osteitis Deformans in a man aged 56. The patient had sustained a fracture of the right femur in the middle of its shaft, and the application of splints and extension not proving successful in keeping the ends in apposition the bone was plated by Mr. T. H. Kellock. This took place in May, 1913. Two months later it was noticed that he was suffering from osteitis deformans, both femora and tibiæ being bowed; the upper part of the spine also was seen to be fixed in a bowed position. The clavicles were enlarged and the bones of the upper extremity were also slightly curved. None of the bones of the head were affected.—The PRESIDENT mentioned that he had had an extremely interesting case of the same nature under his care some years ago. A lady of 63, whom he had known some years before the onset of the disease, was the subject. The disease, from start to finish, lasted four and a half years. It started after an operation for appendicitis, this being her second attack. The first attack occurred six months previously, and the nurse who attended her on both occasions noticed nothing abnormal with her bones. After the operation she complained of rheumatic pains in her legs and thighs, and it was noticed from time to time that she was getting shorter in stature. About four years later the President was called urgently to see her and she had actually fractured her left femur while in the act of stooping to put out a gas-ring. The bone was carefully set and the fragments kept in apposition for six weeks all but two days. She died at this time, and on examining the condition of the seat of fracture after death it was found that no perfect union had taken place. Of the bones of the head none but the point of the chin was enlarged. The President added that Osler mentioned in his text-book that "of 8 cases traced to the end, 5 died with cancer or sarcoma."—Mr. CECIL ROWNTREE said that he had not heard that cases of osteitis deformans were liable to cancer, but he could recall one in which cancer of the tongue occurred. What he had particularly noticed in this case was the very high arterial tension and arterio-sclerosis that existed.—Mr. TAYLOR said that arterio-sclerosis was not present in his case.

Dr. C. M. HINDS HOWELL showed a case of Paraplegia in a woman aged 60. The patient was well till nine months ago, when she complained of pains in the legs and back and weakness of the left leg. Since the onset of symptoms the pains had ceased, but there had been progressive loss of power in the legs combined with loss of sensation. The patient now was unable to stand alone and presented all the signs of spastic paraplegia. She also showed the Brown-Séquard type of paralysis, muscular power being most affected in the left leg, whilst the sensory loss was most noticeable in the right leg. The upper limit of sensory loss pointed to a focal lesion chiefly on the left side of the cord at the fourth thoracic segment. Its nature was almost certainly a tumour. Considering the patient's age Dr. Hinds Howell did not think that he could advise operation unless the patient was very anxious to have it done.

Mr. C. SHATTOCK showed a woman, aged 62 (under the care of Mr. C. C. Choyce), with a Tumour in the Left Groin, noticed for three months, having caused discomfort in walking but no actual pain. There was an elastic mass in the upper part of Scarpa's triangle, free from tenderness, not fixed to skin or bone, and lying behind and to the outer side of the femoral vessels, which were pushed forwards and not involved in the mass. Examination of the hip-joint, spine, bones, and pelvis was negative. The mass was considered to be probably a lipoma.—Mr. TAYLOR thought the diagnosis lay between a lipoma and a fibrous tumour.—Mr. ROWNTREE was in favour of its being a cyst.

Mr. SHATTOCK also showed a man (under the care of Mr. Arthur Edmunds) exhibiting an Aneurysm of the Upper Part of the Radial Artery. There was no history of trauma, but the patient had a positive Wassermann reaction. The swelling had been noticed for three weeks, and was steadily enlarging.—Dr. CAMPBELL remarked that arterial aneurysm did not occur so long as the media remained intact. He drew attention to a function of the muscular elements in the arteries and veins which had been entirely overlooked in this country—i.e., to prevent by their tonic contraction the vessels from undergoing a progressive yielding before the intravascular pressure. Tonically contracted muscle fibre offered a resistance *sui generis* to a stretching force. Were the vessels divested of their muscular (and elastic) elements they would speedily become aneurysmal. From this point of view the veins stood as much in need of muscular tissue as the arteries;[1] those of the lower extremities were rich in muscle on account of the hydrostatic pressure which they had to sustain; the jugular veins contained but little muscle; while the intraocular, intracranial, and interosseous veins were wholly devoid of it, because in their case the intravenous pressure never exceeded the pressure outside. The influence of a tonically contracted media in preventing a yielding of the vessel wall was well shown in the case of the temporal artery. Chronic hypotonus of this vessel led to a yielding of it in the transverse and longitudinal directions; this was the explanation of the dilated and tortuous temporals which were quite frequently present in subjects of low blood pressure.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Fibromyoma.—Laceration of the Perineum and its Operative Treatment.

A MEETING of this section was held on Feb. 6th, Sir WILLIAM J. SMYLY being in the chair.

Sir WILLIAM SMYLY showed a specimen of Fibromyoma removed from a girl aged 21 on whom he had been asked to do an ovariotomy. He did not see the patient until the time of the operation on Jan. 27th, but he did not think he could have made a correct diagnosis even had she come under his observation sooner. When the abdomen was being prepared he felt something like a soft flaccid cyst. On opening the abdomen the uterus and ovaries were found to be healthy. On the right side was the tumour, which was shelled out of the broad ligament. Although it was cyst-like in appearance, on a knife being inserted nothing came out. The tumour was entirely intraligamentous except a very small part embedded in the right wall of the uterus. He had never seen such a large myoma in a girl at such an early age. Pathological examination showed the specimen to be a myoma.

Dr. G. FITZGIBBON described a specimen of myoma which he had recently removed from a patient aged 29. The tumour felt cystic, and on its removal proved to be so. He had considerable doubt at first as to whether it might not be a pregnancy, but after three weeks' observation it was decided to operate. At the operation he felt that there was considerable risk in not removing the whole uterus. One of the difficulties in these cases was the diagnosis, but a greater difficulty was to decide whether the tumour was sarcomatous or a fibroma. He suggested that a second operation would meet the case if the tumour turned out to be a sarcoma, and therefore one should do a myomectomy first.

Dr. E. HASTINGS TWEEDY, in a paper on Laceration of the Perineum and its Operative Treatment, said that in the majority of tears the levator fibres were not severed, but were torn from their attachments to the mid-line of the perineum. This dragging away preceded rupture of the skin and other superficial structures, so that vigorous efforts to support the perineum were often conducted at a time long after its important elements had been torn away. The method of mass suturing with the patient lying on her side could be made an ideal operation. The lowest morbidity percentage rate was seen in the practice of those who conducted obstetrics with least surgical interference, and this truth applied to hospital as well as to private practice. The search for vaginal rents as a routine of treatment increased morbidity. The obstetrician should learn to rely upon himself rather than on his assistants. A slight modification of Lawson Tait's perineorrhaphy was all that was required to bring about perfect adaptation of the levator and other muscles in secondary repair of the perineum.—Dr. FITZGIBBON agreed with the view that it was of importance to lift the tongue of mucous membrane towards the vagina and away from the anus. It was his practice to suture the perineum while the patient was in the lateral position and before the placenta came away, as at that time the anæsthesia was generally sufficiently deep to permit of doing so. An approximation could be made just as well in the lateral position as any other, provided that it did not extend very far into the vagina. In right side tears the dorsal position was necessary for full exposure of the tear. For the majority of tears the lateral position afforded quite a satisfactory view and enabled them to be repaired efficiently. He preferred silkworm gut because it was an advantage to have sutures which would not absorb lochia and carry them into the wound.—Dr. H. JELLETT did not consider that the extent or importance of tears extending up the posterior vaginal wall could be appreciated unless the patient was in such a position that this wall could be clearly seen. Repairing by sutures passed from the perineum alone with the patient in the lateral position had a tendency to leave a tear of the posterior vaginal wall unstitched, so leaving a pouch communicating with the vagina. Even if the perineum suture entered the levator ani muscle, it might very easily miss such part of the vaginal tear as lay above the muscle. The dorsal position was the most suitable for almost every part of obstetrical work, including normal labour: the tendency was towards this practice on the continent and in America. He showed drawings of an operation to illustrate the repair of chronic lacerations of the perineum, and called particular attention to the necessity for suturing the levator ani muscle separately. He had been performing this operation for the last six or seven years, and had quite abandoned the old Lawson Tait operation.—Dr. B. A. H. SOLOMONS thought it necessary that the best way for sewing the ruptured perineum after birth should be determined conclusively so that patients might be left as well before their confinements as afterwards. With regard to the question as to position he always adopted the lateral, except where the vagina was torn very high up and required catgut sutures. He looked with disfavour on catgut in ordinary tears of the perineum and always used silkworm gut.—Dr. D. G. MADILL, referring to the classification of tears, suggested grouping them as—slight tears, large tears, and complete tears. The first healed uniformly, but he found the large tears did not heal up in many cases. He considered that there were objections to suturing lacerations in the second stage which more than counterbalanced the advantages. It was better to wait till the placenta was away before suturing.—Dr. V. J. MCALLISTER considered that in those procedures where the muscles of the pelvic floor were exposed in the process of repair the muscle fibres first met with were not portions of the levator ani, but the remains of the transversus perinei profundus muscles. To display the levator ani muscle satisfactorily one must either retract, or in some cases temporarily divide and reflect the transversus perinei profundus. The levator ani fibres on each side thus exposed he brought together in the middle line in front of the rectum, after which he dealt with the transversus perinei profundus muscles in the same way, uniting them in the middle line superficial to the repaired levator ani muscle.—Sir WILLIAM SMYLY said he regarded the division into three degrees of laceration as of practical importance; the great majority of tears were slight, but there were bad cases in which the muscles were torn, and, as Dr. Tweedy had pointed out, tears through the sphincter muscle formed a distinct group. He preferred operating with the patient in the dorsal position, because, among other reasons, both hands were free, whereas in the lateral the left had to act as a speculum.—Dr. TWEEDY, in reply, said he recognised that the muscles held sutures very badly, and could very easily be cut through, and for this reason he described the operation which took in everything right up to the ischio-rectal fossa; the most elaborate dissection would not enable more tissue to be taken in. In the fresh tear and the old tear the anatomical conditions were precisely similar. He advocated the use of a needle sufficiently long and curved to take in enough fibrous sheath, as it would hold better than muscle. He held that inquisitive midwifery could not be practised without increasing the morbidity rate. He always pinned his faith to the mass suture. The old Lawson Tait operation fell into disuse because it did not bring in the muscles, but the modified form of operation with the curved needle worked admirably.

---

[1] THE LANCET, Feb. 26th, 1910, p. 590.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the Medical Institute, Belfast, on Feb. 12th, Mr. A. B. Mitchell, the President, being in the chair.—Dr. W. Calwell read a paper on Some Less-known Points in Pleural Effusion, which was illustrated by lantern slides. He dealt with the forces within the thorax, first as regarded one lung, and then as regarded the interaction of the lungs upon the mediastinum. A clinical proof was given that fluid did not descend into the complementary pleural sinus in the early stages of effusion, as the pressure was positive as that of the abdomen, not negative as in the lung. A full description of the fissures of the lungs was given, and the importance of the accurate knowledge of their anatomy in cases of interlobar empyemata was insisted on. The possibility of an interlobar serous effusion remaining loculated, as a cause of some of the obscure lung cases, with aberrant signs and ending in recovery, was suggested and its study urged.—Mr. Andrew Fullerton read a paper on the Surgery of the Gall-bladder and Bile Ducts, illustrated by 30 cases without a death. He divided his cases into the following groups. Those in which the gall-bladder was simply drained (15 cases) for calculus, cholecystitis, or chronic pancreatitis. In 11 cases the gall-bladder was removed as a primary operation and in 2 cases as a secondary operation eight and two years respectively after the primary one of simple drainage. Recurrence of symptoms was the cause necessitating the secondary operation. In 4 cases the common duct was incised for the removal of calculi from it or the hepatic duct In 3 of these the duct was drained and in 1 immediate suture of the incision was carried out. In 1 case transduodenal choledochotomy was done for a small stone impacted in the ampulla of Vater. In 1 case the dilated common duct, which could not be emptied through the cystic duct, was anastomosed to the duodenum. This was a case of chronic pancreatitis in which apparently complete obstruction of the common duct was present. The anastomosis was carried out with the help of a small Murphy's button. The patient lived for a year after the operation. The cause of his death was not known to Mr. Fullerton. In 1 case a large subphrenic abscess appeared shortly after cholecystectomy. This was successfully treated by removal of a portion of rib and suture of the diaphragm to the parietal pleura before incision of the abscess. In 2 cases subhepatic abscesses occurred after perforation of the gall-bladder by calculi. In one of these simple drainage was carried out, and in the other the gall-bladder with the calculi was removed. Chronic pancreatitis was present in a marked degree in 5 cases in the series. It was remarkable after operation how rapidly the patients put on flesh. This would seem to signify that the pancreas possessed considerable reparative powers. Mr. Fullerton said that though he had not to record any deaths in this series, he had been favoured with more than the usual amount of luck in several. He could not, of course, count on a continuance of such a mortality rate.—Dr. J. C. Rankin read a paper on the Problem of Tuberculosis as Illustrated by Lupus. An analysis of 100 consecutive cases of lupus coming under Dr. Rankin's treatment showed an incidence as follows: 38 on the nose, 35 on the body, 62 on the cheek, while 35 patients had more than one lesion. Of those starting in the nose practically all had intranasal disease. Eye symptoms were common, usually dacryocystitis. These conditions ante-dated the appearance of the external lupus, often by years, so that taking as evidence of the same diseased process, lacrymation from stoppage of duct, the history of recurring treatment for the eyes, and the difficulty of breathing through the nose, in almost every incidence they were, Dr. Rankin said, brought to a period before puberty. Those cases starting on the body were remarkable for their similarity. Of 12 cases occurring on the hip they all formed circles or segments of circles about a common central point; 17 cases occurring on the wrist showed a point of origin at the back of the joint. The other cases were situated about the other joints. The cases on the cheek started obviously from a submaxillary lymphatic gland and spread in a circle with the main line of advance to the inner canthus of the eye.—In an interesting discussion which took place after the reading of the above communications the following took part:—Dr. J. Campbell, Dr. T. Houston, Dr. R. Campbell, Dr. G. A. Hicks, Dr. O. G. Lowry, Dr. H. Stevenson, Dr. S. T. Irwin, Dr. Calwell, and the President.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Feb. 20th, Dr. David Ross, the President, being in the chair.—Dr. A. Feiling showed three men the subjects of Tabes Dorsalis without the loss of the knee-jerks. The first had had an ulcer on the sole for six months which was now healing. He had had shooting pains for 12 months and some difficulty in micturition; the pupils were unequal and the Argyll-Robertson sign present; slight ataxia and Rombergism were present. There was no known syphilis. In the second case there was inability to retain and void urine normally. The pupils were dilated and sluggish in response to light; there was some analgesia of the arms; the ankle-jerks were absent. There was no known syphilis; Wassermann blood reaction was negative, the spinal fluid positive. Two intravenous injections of neosalvarsan were given without noticeable benefit. In the third case there were pupillary signs without ataxia but with diminished sense of muscle pain in the legs.—Mr. R. C. Elmslie showed: 1. A boy, aged 10 years, whose humerus broke three and a half years ago, through a fall, but at the site of a cyst in the shaft. The fracture healed. The cyst was scraped, but the cavity was not bone filled and seemed to be extending downward. Further measures were proposed to exclude the cyst cavity. 2. A boy, aged 11, with Scoliosis treated by forcible over-correction of the spinal curve by Abbott's method.—Mr. H. J. Curtis showed a woman, aged 54, with a Sarcoma over the Occiput which had perforated the skull. She had also a sarcoma on a rib and advanced mediastinal growth. The skull growth seemed to have been periosteal.—Mr. W. C. G. Ashdowne showed a boy, aged 9 years, who, falling from a van, broke a rib four months ago. Now he stands with body bent forward, thighs semiflexed, and head drooped grizzling. He was placed on a couch and by engaging his attention the flexed thighs were easily placed flat and the spine straight without pain.—Discussion followed as to the diagnosis, opinions varying between fibrosis, sacro-iliac disease, and a functional state.—Dr. P. Hamill showed a woman, aged 62, the subject of Progressive Muscular Atrophy of the Upper Limbs for three and a half years. Fibrillary tremors of the triceps and deltoid were very plain, as was wasting of the thenar and hypothenar eminences.—Mr. P. Maynard Heath showed: (1) A woman with a Primary Chancre of the lower lip; (2) a baby, aged three weeks, with a Hæmatoma over the right parietal and another one over the occipital bone; (3) a woman, aged 29, whose Rib had been Resected and Beck's bismuth paste injected for empyema successfully; and (4) a boy with Birth Palsy of the right arm whose supraspinatus had been beneficially divided.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Feb. 13th, Dr. A. K. Chalmers, the President, being in the chair.—Dr. William Hanna read a paper on the Use of Refrigeration in the Preservation of Foods. After referring to the fact that the United States was not only no longer sending cattle to this country, but was taking for its own supply cattle from countries which had hitherto previously exported almost exclusively to Great Britain, he said that the methods of refrigeration of foodstuffs depended chiefly on the scientific fact that expanding air or vaporising substances, such as sulphurous acid, carbonic acid, or ammonia, in assuming the gaseous form abstracted heat from the atmosphere or other bodies in the neighbourhood. Fresh meat was brought from distant countries either as hard frozen meat or as chilled meat. Chilled meat arrived in a condition ready for consumption and retained the characteristics of fresh meat more closely than frozen meat, but the chilling process required great care and the transport needed constant supervision. The frozen method was the better one as regarded preservation, although it sometimes damaged the cellular and fibrous structure of the meat unless special care was taken in defrosting. Although it had been sometimes said that frozen meat when thawed out more readily decomposed, yet experience showed that it would keep with proper care as well as freshly killed meat after being taken from the refrigerator even in high temperature. Referring to the conditions of unsoundness which were found as the result of inspections made under the foreign meat and unsound food regulations, Dr. Hanna stated that, owing to the very good inspection carried out at the present time in nearly all the exporting countries, the proportion of diseased meat arriving in this country was very small. Tuberculosis was found in animals from nearly all exporting countries, but as a rule the lesions were such that in many cases they might be overlooked with the best inspection. Out of 59,000 carcasses of pigs imported during three years into Liverpool from China only 541 were found to be affected with tuberculosis after a very complete examination of every carcass. Through some fault in the process of refrigeration moulds were frequently found on refrigerated meat, poultry, game, or fruit. If the mould were present in only small amount it would suffice to remove the superficial part of the meat or substance affected, but if it had reached a large amount it would be necessary to take into consideration the possibility of decomposition in the underlying flesh associated with bacteria. Dr. Hanna considered that refrigeration afforded a ready means of obtaining a plentiful and cheap supply of food, and he thought that every means was now being taken to obtain and keep this supply wholesome by the constant attention of the producer abroad to the methods of inspection and handling and by its thorough examination on landing in this country.—Dr. A. W. J. MacFadden referred to the possible desirability of limiting the time during which cold storage should take place. In the United States regulations with respect to this had been made, but in this country it was probable that storage was not prolonged beyond the period when it would be undesirable to continue it.—Sir Shirley Murphy spoke of the effect of cold storage on the flavour of meat, and thought that the process might even improve the flavour.—Dr. R. Dudfield considered that the time had come when the use of preservatives in milk and cream should be stopped and refrigerating processes should take their place.

UNITED SERVICES MEDICAL SOCIETY.—At a meeting of this society held at the Royal Army Medical College, Grosvenor-road, S.W., on Feb. 12th, Colonel S. Westcott, C.M.G., A.M.S., read a paper on the Siege of Ladysmith. After giving a general sketch of the military arrangements for the defence of the town, Colonel Westcott said he was first placed in medical charge of the convent, which had been equipped for the treatment of the wounded, and described some of the most interesting cases that came under his care while at the convent. Later, as a consequence of the removal of the sick and wounded together with the sick women and children to the neutral camp at Intombi, the medical arrangements were modified, and he was appointed secretary to the principal medical officer of this camp. Colonel Westcott described the arrangements made for treating the sick and wounded at Intombi, and the difficulty of the task owing chiefly to want of sufficient *personnel*. On Nov. 11th the first two cases of enteric fever arrived, heralding an outbreak that eventually totalled up to 2250; when one added to this 2000 cases of dysentery, not to mention the wounded and other cases of illness, the difficulty of caring for these with a medical establishment of 22 officers, 32 nursing sisters, 38 non-commissioned officers, and 305 orderlies, of which only 69 were trained men, could be appreciated. In addition there was a large staff of Indian and Kaffir labourers whose duties were scavenging, refuse removal, laundry work, and grave-digging, &c., and these needed constant supervision. At the commencement of the siege a long investment was not anticipated, and the food-supply was thought to be sufficient; with the delay in the arrival of the expected relief and the reverses to Buller's force, the rations were gradually cut down, until on Jan. 28th the ordinary ration was 1 lb. of bread made from wheat or maize, 1 lb. of horse or mule meat, ¼ oz. tea, 1⅓ oz. sugar; vinegar was used as an antiscorbutic instead of lime juice, and there was no milk except for the sick. Colonel Westcott described the various rations that were used for the sick. Of drugs there was plenty. He discussed the mode of development of the outbreak of enteric fever and the causes that led to its continuation. The speaker noted that penetrating abdominal wounds were not nearly as fatal as one would have expected, and read notes of cases of these injuries. Colonel Westcott concluded his most interesting paper with a word of tribute to the high qualities of the late General Sir George White and Colonel, now Sir Edward Ward, Bart.

CARDIFF MEDICAL SOCIETY.—A meeting of this society was held on Feb. 10th. The following cases and specimens were shown:—Dr. E. J. Maclean: An Ectopic Gestation from the right side. A corresponding condition had occurred in the same patient on the left side a few years before.—Mr. William Sheen: A patient who had had Hemithyroidectomy performed eight days before. The transverse scar was in the fold of the neck, and was already quite inconspicuous.—Mr. J. W. Geary Grant: A child with Syndactyly on both hands. There was separation of the proximal portions of the digits, but clubbing and adhesion of the terminal parts. No other members of the family had any developmental errors.—Mr. Sheen made a communication on Bullet Wounds, referring particularly to those occurring in civil practice. He described the various weapons and projectiles used, from the toy pistol to the latest military weapons, and including a description of sporting guns and cartridges. He also showed a number of cartridges from the Bulgarian war. After indicating the various factors which determined the amount of damage, Mr. Sheen went on to describe and illustrate the best methods of localising and removing bullets lodged in the tissues. He showed the telephone probe, including a modification which he had devised, where the same pair of forceps detected and extracted the bullet. Finally, he briefly described a number of illustrative cases.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at St. John's Hospital, Leicester-square, on Feb. 17th, Dr. Morgan Dockrell being in the chair.—Dr. J. L. Bunch showed a case of Para-Psoriasis in a man aged 47; the lesions were circumscribed on both legs with an absence of the eruptions on the knees and elbows; also a case of Pityriasis Rubra in a boy aged 19, and a case of Varicella in a child.—Dr. W. Griffith showed a case of Fungating Syphilis affecting the scalp; the patient had received an intramuscular injection of salvarsan (0·6 grm.) 24 hours previous; the lesions were drying up very rapidly.—Dr. J. L. Phibbs showed two cases of Syphilis.—Dr. Dockrell showed a case of Lichen Hypertrophicus, the eruption affecting the bends of both legs, and a localised patch was present on the thigh; also a boy with a Bullous Eruption which had improved considerably under vaccine treatment.—The discussion on bullous eruptions was adjourned.

THE CANCER HOSPITAL.—The annual meeting of governors of the Cancer Hospital, Fulham-road, London, was held on Feb. 23rd, Lord Northbrook presiding. The committee in their sixty-third annual report stated that during 1913 the number of patients admitted to the wards was 787, an increase of 97 on the preceding year's total, while in the out-patients' department 990 new cases were treated, the total attendance numbering 14,308. The committee also reported that after carefully going into the matter of the provision of further accommodation they had adopted a scheme for the extension of the east end of the building whereby an extra 20 beds would be provided. The work will be put in hand at once, and the cost of the building will be about £7000, the upkeep of the extra beds being about £2000 a year. The financial statement showed an excess of expenditure over income during the year of £8048 2*s*. 2*d*. Legacies to the amount of £20,788 had been received during the year. Lord Northbrook was re-elected president of the hospital, and the other officers were reappointed. Mr. Charles Ryall, responding to a vote of thanks to the honorary medical staff, spoke of the effect of radium in the treatment of cancer. He said they were going through the experimental stage of radium treatment, and there was an enormous field of research and treatment amongst the patients at the hospital, but they were hampered by the inadequate quantity of radium at their disposal, and their inability to procure more owing to its scarcity and enormous cost.

Reviews and Notices of Books.

Blood Pressure in General Practice.

By PERCIVAL NICHOLSON, M.D. London and Philadelphia: J. B. Lippincott Company. 1913. Pp. 157. Price 6*s*. net.

THE estimation of blood pressure by means of mechanical methods has recently been much more extensively employed than was formerly the case. The usual manner of judging the arterial tension in actual practice has, of course, been by digital pressure, but by means of the sphygmomanometer permanent exact records may be obtained. The result on any occasion may thus easily be compared with that obtained at other times. Some experience is necessary before accurate readings and interpretations can be obtained, and Dr. Nicholson's object in writing this work has been to furnish to the general practitioner a short treatise on blood pressure entirely from the standpoint of its practical significance and value. He has reviewed the literature on the subject, and has utilised such materials as he deemed of clinical value, avoiding what are as yet purely theoretical considerations.

In the first chapter the technique is explained, stress being laid on the auscultation method, by which not only the systolic but also the diastolic and pulse pressures can be accurately determined. After a description of the principal forms of instruments that have been introduced, the physiological factors involved are discussed, one point being especially emphasised—namely, that the maximum, or systolic, pressure by itself indicates mainly heart strength, but equally, if not more, important the peripheral resistance is shown by the minimum, or diastolic, pressure. In the past comparatively little work has been done on diastolic and pulse pressures—a fact due largely to the difficulty in obtaining reliable readings with the instruments available and the methods used, but Dr. Nicholson maintains that this is no longer the case when the auscultatory method is utilised. In the chapter on hypertension the various morbid states that may produce this condition are mentioned. It is, of course, of importance to discover these causes of high blood pressure early, as they may determine the onset of a condition which, if continued, will cause serious and permanent changes in the vessel walls, which in turn produce cardiac hypertrophy with its subsequent weakening, and followed by failure of compensation. The remarks on hypotension also will be found of interest, and numerous suggestions are made in reference to treatment.

There is not much that is original in this work, but for those engaged in general practice it will be found useful in providing information in regard to blood pressure which it would take some time to obtain from the literature on the subject, published as it is mainly in journals and text-books on general medicine.

Geschichte der Biologischen Theorien in der Neuzeit.

Von Dr. EM. RÁDL. I. Theil. 2. gänzlich umgearbeitete Auflage. Leipzig und Berlin: Wilhelm Engelmann. 1913. Pp. 351. Price, paper, 9 marks; bound, 10 marks.

THE first edition of this work was published eight years ago, and it undoubtedly is the most comprehensive experiment made, since G. Carus in 1876 published his well-known "History of Zoology," to give a detailed account of what the author calls the history of biological problems in modern times.

A short introductory chapter deals with the long bygone past and the Middle Ages, in which the author rapidly sketches the story of Hippocrates, Plato, Aristotle, Pliny, Galen, and their doctrines. A brief account is given of the origin of the earliest universities and of science amongst the laity, as represented by Albert the Great. This brings us to the chapter on the Renaissance, a singularly interesting one. Dante (1265–1321), Petrarca (1304–1374), and the invention of printing (1450) lead the author up to a very full account of Paracelsus, who was born in Maria-Einsiedeln, near Zürich, in 1493, just a year after Columbus discovered America. The career of this extraordinary man is set forth in full detail and with critical appreciation, including his period as professor in Basle (1526–28); his wanderings to and fro in Europe, his death in Salzburg in 1541 at the age of 48, his doctrines and his fantastic absurdities, his efforts to introduce simple chemical preparations instead of complicated decoctions of plants. To his medicaments he gave sometimes old names, but endowed those names with a new significance—i.e., arcanum, elixir of life, quinta essentia, mercurius vitæ. Surgery he threw overboard, and a foreign body embedded in a wound was not to be removed if it could not be removed simply by means of the fingers. The author's conclusion is that Paracelsus was a "biological philosopher," but no Titan and no superman, and he has been called "Lutherus Medicorum." The whole account of Paracelsus, which runs to nearly 70 pages, is most interesting.

This brings us to the "Dawn of Modern Science," with an account of Vesalius, Leonardo da Vinci (1452–1519), and Severino, professor of anatomy and surgery in Naples (1580-1656). Then we are given an account of the new Aristotelians, as represented by Cesalpinus of Pisa (1519-1603) and Harvey (1578-1657). Due weight is given to Harvey's work on embryology, a contribution to this department which is sometimes apt to be forgotten in view of his greater demonstration—the circulation of the blood. The account of Francis Glisson (1597-1677) and the Encyclopædists brings the reader to "the foundation of new scientific methods." The work of Leonardo, Galileo, Bacon, Descartes, Borelli, and Willis is successively considered, and then we come to the labours and achievements in the seventeenth century of Redi, Malpighi, Swammerdam, and Leeuwenhoek, and in the eighteenth century of Réaumur and Spallanzani. There is a short chapter on the Paracelcists as represented by van Helmont, and another on the Vitalists as represented by von Stahl of Halle (1660-1734) and Bichat (1771-1802). The rise of biology in the eighteenth century is next considered, including an account of the doctrines, influences, and work of Leibnitz, Ch. Bonnet, and A. von Haller. Epigenesis, cell theories, and the changes that take place in the germinal layers of the blastoderm form the basis of another chapter. The work of Linnaeus, Buffon, and "French morphology" are successively passed in review. Under "French morphology" we have an account of the origin of morphology—human, animal, and botanical—as represented by the work of Cuvier and Geoffroy St. Hilaire. This brings Part I. to an end.

This work is, so far as we know, the only one of its kind, and we heartily congratulate the author on it. He shows, by his luminous notes and references, as well as by the critical acumen to be found throughout its pages, his equipment for a difficult task. We look forward with pleasure to the appearance of the second part. We should state, although the author does not mention the fact, that he is *privat-docent* of the history of the biological sciences in the University of Prague.

LIBRARY TABLE.

Noted Murder Mysteries. By PHILIP CURTIN. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1914. Pp. 302. Price 7s. 6d. net.—The literature of famous crimes is growing apace, but Mr. Philip Curtin's book is in a different category from any other book that we have met with, written on the ever-fascinating subject of murder. Nine stories are here told with great literary dexterity, only the essential facts of each case being mentioned, and for these it should be said that the author has gone, where possible, directly to authoritative sources. The crimes which are treated of have been selected because, when all the available evidence is viewed and reviewed, there are features in them which are inexplicable. The mystery of these murders is not so much that doubt is present as to the perpetrator, as that the character, whether of the aggressor or of the victim, renders the circumstances of the murder inexplicable. Each narrative is made to point a short moral, these being indicated by such sub-titles as "Can a Wife Love too Well?" this being the terrible assassination of the Duchess of Praslin; "The Unwanted Child," this being the curious acquittal of the Marquis de Nayve of the murder of his wife's illegitimate son; "Where Platonic Love may Lead," this being the famous crime of the Peltzer brothers. Another point that all the fearsome episodes have in common, as well as their incomprehensible psychology, is the fact that all centre round women. The author finds that in the study of murder it becomes more and more apparent, as we look deeper into the origins of each event, that, in all those cases which come to be elevated to the position of famous murder mysteries, a large part is played by some form of illicit love. The mystery of the death of Charles Bravo certainly depended for its obscure features upon Mrs. Bravo's unintelligible intrigue between her first and second marriages. If the extraordinary story of Mrs. Bravo's amatory escapade had not come out a verdict of death by misadventure would probably have been returned. On the other hand, the story as the jury heard it furnished no logical reasons for murder or suicide. The part played by illicit love in the cases of Madeleine Smith, the Marquis de Nayve, Henri Chambige, and Edith Carew is obvious, while in the two best stories regarded simply as sensational plots, the De la Pommerais affair and the Peltzer affair, sex also played its part. These two stories are far less familiar to English readers than are the mysteries of Marie Lafarge and Madeleine Smith, but as a ready-made scenario for a dectective novel it is extraordinary that one or other of them should not have been elaborated into a famous sensational romance. The invention by the Peltzer brothers of a murderer, who had a name, an address, a business, and a fairly large personal acquaintance, but who had no existence, reads like a typical Gaboriau scheme; while Wilkie Collins would have revelled in the situation created by De la Pommerais, when he persuaded his victim to poison herself. It is much to the credit of Mr. Philip Curtin that within the limits of a few pages he has been able to make the stories of these two elaborate crimes quite lucid. If he is not a novelist he had better become one at once.

A Course of Lectures on Medicine to Nurses. By HERBERT E. CUFF, M.D. Lond., F.R.C.S. Eng., Medical Officer for General Purposes to the Metropolitan Asylums Board. Sixth edition. London: J. and A. Churchill. 1913. Pp. 281. Price 3*s.* 6*d.*—The object of the author has been to provide a book of reference for nurses which will enable them intelligently to follow the progress of their cases, to grasp the meaning of symptoms, to understand some of the reasons which influence the physician in his adoption of different methods of treatment, and the results to be expected therefrom. In this endeavour he has succeeded well. To avoid becoming a mere machine a nurse should know something about the anatomy and physiology of the affected organ, and should have an elementary knowledge of the changes produced by disease, to enable her to understand the various points necessary for carrying out her instructions efficiently. Dr. Cuff has in no way overstepped the mark, and has written neither too much nor too little. The book can be recommended to those for whom it has been written.

Annals of Tropical Medicine and Parasitology. Series T.M. Vol. VII., No. 4.—No fewer than 12 contributions, all of scientific interest or practical value, are included in this number of the Annals. The first article is entitled "Studies in Blackwater Fever," by Professor J. W. W. Stephens, of Liverpool University, who considers in it some of the most important factors bearing upon the malarial origin of the disease, collected by him after a thorough examination of recent literature on the subject. A long list of references is given as well as a number of statistical tables.—Dr. John Gordon Thomson and Dr. David Thomson give the results of their researches on the growth and sporulation of the benign and malignant tertian malaria parasites in the culture tube and in the human host. This line of investigation was in the first instance suggested to these workers by Sir Ronald Ross, and it is of interest to know that they were able to cultivate the malignant tertian parasite on 12 occasions after the method of Bass and Johns, and the benign tertian three times. This paper is illustrated by a coloured plate showing the cultural forms of malarial parasites and by some microphotographs demonstrating the sporulation of the malignant tertian parasite.—The Trichonocardiases (fungus affections of the human hair), of which three varieties have been met with in the Anglo-Egyptian Sudan, form the subject of a joint paper by Dr. Albert J. Chalmers, Director of the Wellcome Tropical Research Laboratory, Khartoum, and Captain W. R. O'Farrell, R.A.M.C., protozoologist to the same institution. The causal agent of this hair affection of the axilla or pubis in man is Nococardia tenuis (Castellani, 1911) either alone or in association with other organisms. This paper is illustrated by a coloured plate and several microphotographs.—Dr. Chalmers, together with Captain A. D. Stirling, R.A.M.C., senior medical officer with the British troops at Khartoum, describes an interesting epidemic of trichonocardiasis which occurred in the Welsh Regiment while stationed at Khartoum; 42 soldiers were affected, the disease spreading from man to man. The primary cause of the outbreak was traced to an infected washerman employed by the regiment.—Hereditary infection, with special reference to its occurrence in the hyalomma Ægyptum infected with crithidia hyalommæ, is the subject of an article by Captain O'Farrell, illustrated by three plates. Crithidia hyalommæ is a flagellate parasite occurring in the hæmocœlic fluid, salivary glands, ovary, oviducts, and ova of hyalomma Ægyptum, the common cattle tick of the Anglo-Egyptian Sudan.—Dr. B. Blacklock and Dr. Warrington Yorke supply a paper on trypanosoma vivax in rabbits, and the same authors discuss in a second contribution the probable identity of trypanosoma congolense (Broden) and T. nanum (Laveran); their investigations lead these experts to express the opinion that in the present state of our knowledge we can only conclude that T. congolense and T. nanum are the same parasite.—The pathogenicity of nosema apis to insects other than hive-bees is discussed by Dr. H. B. Fantham, D.Sc., and Dr. Annie Porter, D.Sc. These investigators believe that the "bee disease" is pathogenic to other kinds of bees as well as to wasps, some butterflies and moths, blowflies and crane-flies, and the sheep "ked."—The same two experts furnish an article on Herpetomonas stratiomyiæ, n.sp., a flagellate parasite of the flies stratiomyia chamelon and S. potamida, with remarks on the biology of the hosts (illustrated).—Mr. Henry F. Carter, F.E.S., contributes a paper on certain mosquitoes of the genera Banksinella (Theobald) and Tæniorhynchus (Arribalzaga), and Mr. Fred. Theobald, F.E.S., supplies a description of new culicidæ from the Sudan.—Dr. J. G. Thomson and Dr. Fantham publish in a paper the preliminary results of their investigations on the cultural forms of Babesia (piroplasma) canis *in vitro*. These experts succeeded in cultivating this organism in two out of four attempts, employing the method described by Bass. This contribution is illustrated by several microphotographs. This number concludes the seventh volume of the Annals, a table of contents and an index being appended.

Lectures on Medical Electricity to Nurses. By J. DELPRATT HARRIS, M.D. Durh., M.R.C.S. Eng., Senior Surgeon and Medical Officer in Charge of the Electrical Department, Royal Devon and Exeter Hospital. London: H. K. Lewis. 1913. Pp. 88. Price 2*s.* 6*d.* net.—This manual is intended for hospital trained nurses seeking employment in the electrical department of a hospital or undertaking the treatment of a private patient under the supervision of a medical man. It is written in a clear and elementary manner and covers every branch of work likely to be demanded of those for whom it is intended. It is not meant for medical men, but doubtless many electro-medical specialists and others will be glad to know that such a book is available to put into the hands of those who work under them. Chapters are given on the X rays, Finsen light, high-frequency currents, and diathermy.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. VII., No. 26. January, 1914. Oxford: At the Clarendon Press. Subscription price 25*s.* per annum; single numbers 8*s.* 6*d.* net each.—The contents of this number are: 1. Intracranial Serous Effusions of Inflammatory Origin, by W. B. Warrington.

It is claimed that the progress of an inflammatory effusion within the sk [illegible] that the effusion may [illegible] that the symptoms m [illegible] of brain disease It is suggested that the primary cause may be a near or distant focus of septic infection, and that the toxins not the micro organisms, lead to the formation of excess of fluid —2 The Experimental Formation of Acute Gastric Ulcers, by T R Elliott In the course of some experiments with tetrahydro β naphthylamine hydrochloride it was found that when injected subcutaneously into guinea pigs it caused the formation of acute gastric ulcers These were due to the action of the gastric juice on the damaged mucous membrane They form in one or two hours, and heal with great rapidity unless they become septic Repair epithelium covers the raw surface within three days, and from this the glands are regenerated later —3 *A Contribution to the Study of Bronzed Diabetes, by* J F. Gaskell, A F Sladden, R L Mackenzie Wallis, P T Vaile, and A E Garrod A careful and detailed record of the clinical, pathological, and chemical features of a case of this disease, together with an account of necropsy and histological examination of the organs, is given Some interesting general observations upon the nature of the disease are also appended —4 On the Infective Nature of Certain Cases of Splenomegaly and Banti's Disease by A G Gibson In the spleen of six cases, three with the picture of Banti's disease, two with splenic enlargement and fibrosis, and one with splenomegaly, there were found appearances suggesting the parasitic invasion of the organ by a streptothrix organism —5 *On Pneumo pericardium, by* John Cowan, Archibald W Harrington, and J R Riddell—an interesting record of a case of pneumo pericardium, with some admirable reproductions of skiagrams, through which the condition was diagnosed These appear to be very rare at present, the only other published being that of Wenckebach's case of artificial pneumo pericardium —6 Critical Review The Pituitary Body, by Emil Goetsch A useful critical summary of the present state of our knowledge in regard to the structure, functions, and pathology of the pituitary body is given, together with a bibliography

The Military Surgeon Published by the Association of Military Surgeons of the United States, Washington, D C Editor, Major CHARLES LYNCH, U S Army Price $3 50 per [illegible]

the year was the lowest on record (not precisely stated, but apparently 25 5 per 1000) The sick rate from disease was 39 85 per 1000 in the Philippines and 22 57 in the United States, the difference is supposed to be the effect of tropical service The admission rate was 823 94 also the lowest on record The invaliding rate has decreased, in part because men can no longer be invalided [illegible] but must be brought before a boa [illegible] of the hospital corps is displayed [illegible] *fourth of the numbers required* [illegible] has now a good shoe thanks to a committee of which Major E L Munson, of the Medical Corps, was president From the Philippines it is reported that "many skin lesions of the leg are due to the constant wearing of leggings" According to the report of the Surgeon General of the United States Navy for the fiscal year 1913 the rates in the navy also appear unusually low, the daily sick rate being 25 9, and the admission rate 787 per 1000 Deaths have also decreased Typhoid inoculation has justified itself, in 80 000 completely inoculated only 7 cases had occurred, and of these 4 were in the same small tropical station where the vaccine used had deteriorated An increase in the *admissions for venereal disease is reported, but the number* of days under treatment is lessened and that is thought due to prophylactic measures, which if used within six hours will prevent venereal disease It is recommended that prophylactic packets be put on sale in ships' canteens and that all persons on the sick list for venereal disease shall forfeit their pay The advantage of this last recommendation has been long considered chimerical; it must be the frequent inspections which have brought it again into practical politics A medical reserve corps has been formed, but the medical department of 292 officers is 55 (16 per cent) below strength Thirty-four recommendations close the abstract, of them we may note (1) that receiving ships be abolished and their crews sent to naval barracks which should be built, (2) barracks in dockyards to take the crews of all ships undergoing long refits, (3) boards to report on the best illumination of ships and on "crew's heads" (water closets), (4) a hospital ship for each fleet, (5) for each ship a sanitary barber's shop a garbage destructor, and a laundry, (6) no drugs to be sold in canteens, (7) identification labels to be worn by officers and men during every battle drill (general quarters); (8) short courses for medical officers, (9) white uniform to be replaced by khaki, and (10) the abandonment of the Naval Tuberculosis Sanatorium at Las Animas, Colorado, though earlier in the report its results are stated as "in a large proportion of cases gratifying" Some of these recommendations will introduce English practices into the United States navy, and on the other hand others here made have long been desired by our own naval medical officers In the National Guard of the United States (the *territorial volunteers), antityphoid vaccination is being more* and more used, in some corps recruits have to be vaccinated before enlistment "To overcome the evil influence of 'devil doctors' in Samoa the commandant of the naval station at Tutuil has established clinics for natives" A special campaign against trachoma is being undertaken in Kentucky, an unusual note states that an officer of the public health service has been detailed to ascertain "the cause of the high rate of physical efficiency of certain" Government printers Now that it has been made difficult to procure opium and cocaine in the United States many drug victims have turned to heroin the sale of which is not as yet carefully restricted under State laws —*A very important address on Medical* Ethnology, by Lieutenant Colonel C E Woodruff, should be carefully read, we can only touch here on one point—the importance of skin pigment to animals and men in countries of bright sunshine The white domestic pig cannot survive in lands with intense sunshine nor can white fox terriers or other pets be acclimatised in India All tropical animals have dark skins as a protection against light Man is little more independent of his climatic environment, different races have vitality varying in different climates and stand up differently against infections In Portland, Oregon (latitude of Bordeaux) Scandinavians resist tubercle well, but in Los Angeles California (latitude of Agadir), they succumb *quickly, though Italians show there good resistance* The Baltic type of man, like an Alpine plant, wants a certain latitude or altitude, or a certain cloudiness, as protection from light (shown by statistics produced from various sanatoriums and otherwise) The triumphant Vandals did not last two centuries in Northern Africa The Baltic stock survives in the mountains of Tennessee but has died out in Louisiana, and is not holding its own even in the St Lawrence Valley The climate of the United States does not suit blondes Colonel Woodruff has never seen a yellow haired soldier in the United States Army who had ancestors in the country before 1848, the students, too in New England Universities are all dark Hippocrates noted how phthisis in the Mediterranean killed fair people Nature does not alter individuals, it kills those who are unsuitable The practical conclusion is that we should more carefully choose the climate to which we send consumptives and other invalids, not sending blondes to places of bright sunshine nor brunettes to cloudy districts

MISCELLANEOUS VOLUMES.

AMONG the miscellaneous volumes calling for notice this week industrial effort claims two books on dairying, reminiscence lends a page to the history of the New [illegible] elf in a book of [illegible] the hard facts of [illegible] handbooks and a [illegible]

British and Colonial Dairying, by G SUTHERLAND THOMSON, F R S Edin (London Crosby Lockwood and Son 1913 Pp 464 Price 9*s*), is intended for school, farm, and factory use, and it presents a very good account of the dairy methods pursued not only in this country but also in the colonies References to dairy *development could* scarcely be complete without an allusion to the busy milk countries Denmark and Sweden, and in Chapter VIII some interesting particulars in regard to the policy of Danish and Swedish milk industries are given The subject is treated from both a practical and scientific standpoint, and the author's account will be of value to dairy farmers and others concerned in the industrial preparation of dairy products.—— A kindred booklet is *Farm and Creamery Buttermaking*, by C. W. WALKER-TISDALE, F.C.S., and THEODORE R. ROBINSON, F.S.I. (London: The "Dairy World" Office. 1913. Pp. 194. Price 3*s.* 6*d.* net). This is a capital little guide for prospective buttermakers. The treatment of the subject is both practical and scientific. Thus there are useful directions given for the analytical examination of dairy products, while their practical management is clearly set forth. Cleanliness is very properly insisted upon throughout.

From his recollections of the now distant New Zealand war in the "sixties," and his more recent experiences in Natal and the Transvaal, Colonel G. HAMILTON-BROWNE has put together in *Camp Fire Yarns of the Lost Legion* (London: T. Werner Laurie, Limited. Illustrated. 1913. Pp. 301. Price 12*s.* 6*d.*), a cheery and gossiping volume of amusing stories and tales of adventure. Some of these are distinctly thrilling, being first-hand accounts of fighting against odds and marvellous escapes in the New Zealand operations, and again in Zululand. The accounts of being lost in the Bush, one of the author's own adventures in New Zealand, and the other of two instances in South Africa, are most realistic.

A pleasing little book of song by "A PHYSICIAN" is *Time and the Timeless* (London: Henry J. Glaisher. 1914. Pp. 95. Price 2*s.* 6*d.* net), described by the author as Songs of Shadow and of Hope. It consists of many charming, and not a few deep, thoughts expressed in smooth and flowing verse. The author has the "lyric lilt." Some of the numbers have a medical theme—"This Little Bistoury," "In Memoriam: Sir Andrew Clark," "To a Brother Physician." We quote the author's introductory verse—

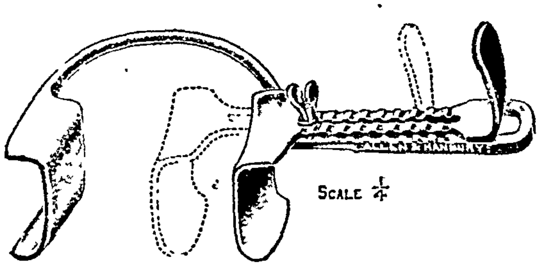
> A few stray flowers of Song
> Found in my garden. Call them only weeds,
> But Nature sowed the seeds,
> And unto her do they belong.

The twenty-fifth annual issue of the *Public Schools Year Book, 1914*, edited by H. F. W. DEANE, M.A., F.S.A., and W. A. EVANS, M.A. (London: The Year Book Press. Pp. xxxii.-835. Price 5*s.* net), contains information likely to be sought by parents, schoolmasters, and others. The first part of the book is devoted to a summary of the proceedings at the last Headmasters' Conference, and this is followed by a list of public schools, with particulars of the governing bodies, staffs, admission, entrance examinations, fees, prizes, and so forth; while the second part gives details of scholarships at the public schools, examinations for entrance to the universities, and conditions of admission to the navy, army, Civil Service, and other professions. Lists of preparatory schools, with particulars relating to them, and articles on various professions, as well as lists of school books, are included among the excellent features of this publication.—— Although *The International Whitaker* (London: Messrs. Whitaker; New York: The International News Company. 1914. Pp. 511. Price 2*s.*) is only in its second year, its merits have given it a place equal with that of the more local publication from which it takes its name. It contains information with regard to the geography (physical and political) of all the countries of the world, compiled from official sources; and in many cases revised by Government departments. There is an index of 36 pages, making reference to statistical, geographical, and commercial information concerning the whole world easily accessible. The crude linen cover of last year has given place to a neat cloth binding and the corners of the book have been rounded.—— *Herbert Fry's Royal Guide to the London Charities*, edited by Mr. JOHN LANE (London: Chatto and Windus. 1914. Pp. 359. Price 1*s.* 6*d.*), gives in alphabetical order the name, date of foundation, address, objects, annual income, chief officials, and so forth, of the various charities of London. The preface contains a valuable summary of the large charitable donations and bequests of the past year.—— In THE LANCET of August 3rd, 1912, p. 298, we noticed a little twopenny pamphlet by Dr. J. T. RICHARDS, of Battersea, entitled *National Health Insurance, a Plain Exposition of the Act*, in which the writer, putting himself in the position of the insurable person, discusses what his payments are to be, how they are to be made, what the benefits are, and how they are to be obtained. This pamphlet has now reached a fourth edition, and is published in two forms—first, as before, price 2*d.*, with the changes made in the Amending Act, 1913; and secondly, price 6*d.*, with marginal references to the sections of the Acts from which the condensed statement is made. The pamphlet is merely explanatory, not argumentative, and can be cordially recommended.

New Inventions.

A SEMI-AUTOMATIC ABDOMINAL RETRACTOR.

THIS instrument, a modification of the well-known Edmunds's retractor, consists, essentially, of two parts: (1) the main portion—i.e., a handle with hoop and blade, which retracts towards the surgeon; and (2) a detachable shaft with a different sized blade at either end. When one blade is used for retracting the other serves as an adjusting handle. The two are united by a screw joint at the shoulder of the main portion. To prevent any slip the contact surfaces of the two parts are serrated, one turn of the screw being sufficient to lock the retractor at any required degreee of retraction. The advantages of this instrument are, first, it can be used as an easily adjusted automatic retractor, any slip being quite impossible. Secondly, if the anæsthesia is not giving sufficient stability of abdominal muscles the assistant can steady the instrument by means of the handle. He can also manipulate it to give exposure to any region of the operation field, as required by the surgeon, on either side of the incision. This frequently eliminates the necessity of two or more assistants being called upon to retract. Thirdly, the lipping on the retracting blades allows the abdominal walls to be well held up for the purpose of reducing intestines.



Messrs. Allen and Hanburys, Wigmore-street, London, W., are making this instrument for me.

Portland Court, W. JOHN EVERIDGE, F.R.C.S. Eng.

THE HAMILTON COMBINED CANTEEN AND FILTER.

THE construction and arrangement of this combined canteen and filter were described in THE LANCET of Oct. 7th, 1911. Since this notice appeared Miss O. M. Hamilton, its inventor, has obtained a bacteriological report upon its germ-filtering efficiency from Dr. John Eyre, of the Bacteriological Laboratories, Guy's Hospital. The report shows that the porous candle used filters rapidly and gives a sterile filtrate. Bacillus prodigiosus (an organism much smaller than typhoid and dysentery germs) only came through in appreciable numbers on the fifth day. In one experiment the original water in the canteen contained 15,000,000 B. prodigiosus per cubic centimetre. These results speak well for the filtering power of the porous material employed. The canteen is a small curve-shaped cistern in which is suspended a protected case enclosing the germ-proof filtering cylinder. All parts are easily detachable and therefore cleaned, while the efficiency of the filter can be ensured by mechanical cleaning and by placing it in boiling water when that is available. An important feature consists in the provision made for drawing the water by suction. As we pointed out before, the soldier does not drink from it by tipping the apparatus to his lips as from an ordinary drinking utensil, but by drawing the water from a nipple at the top by suction. It is a very neat and compact apparatus.

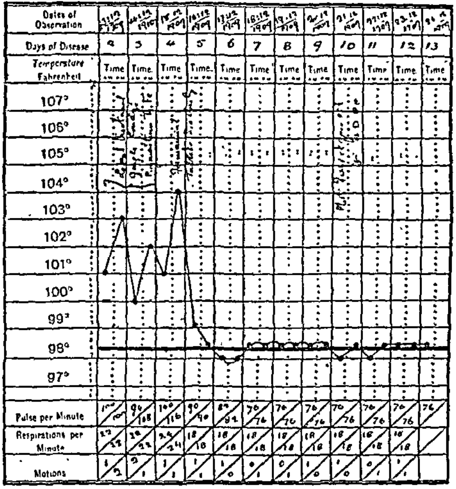
The Value of Formamint in Reducing the Temperature of Tonsillitis.

From the "Medical Times," Sept. 24th, 1910.

CASE II.

Suppuration of both Tonsils.

"This was of a very severe character, there being several foci of suppuration on the left tonsil, and one large one on the right. Local applications of warm fomentations, warm gargles of . . . . . . lotion, and painting the tonsils and fauces with pigmentum ferri perchloridi had absolutely no effect. Formamint rode over the whole difficulty immediately, and a morbid pathological condition was soon converted to a healthy physiological state."



The rapid rise of temperature which is so characteristic of Tonsillitis, and often disturbs the peace of mind of the patient's relatives by causing a more or less marked delirium, yields rapidly to the exhibition of Formamint Wulfing, as the above chart, selected from several published in the "Medical Times," strikingly demonstrates.

In another case, a patient with temperature of 103° F. at 4 p.m., bad headache, huskiness of voice, who was only able to swallow a few ounces of milk with pain and difficulty, was ordered two Formamint Tablets four times a day. At 9 p.m. the temperature had dropped to 99° F.; the huskiness and headache had gone; he drank 12 ounces of milk without any discomfort, and stated that he was feeling fine. By next morning his temperature was normal, the size of the tonsils and congestion of the fauces had considerably diminished, and he made an uninterrupted and rapid recovery.

Similar results have been reported by many other observers, notably Dr. H. Schoppler, in a German Military Hospital, who published a remarkable set of cases in the "Reichs Medizinal Anzeiger." He proved that, **"when Formamint was given, the patients recovered on an average in four days, whereas, with gargles only, eight days are required to effect a cure."** In many cases, patients admitted to hospital on one day were discharged fit for service on the following day.

The rapid subsidence of the temperature was accompanied by the equally prompt disappearance of all other discomforts to which sufferers from Tonsillitis are subject.

The apparent antipyretic action of Formamint Wulfing is due to the germicidal action of the nascent formaldehyde evolved in the mouth when the tablets are sucked. The bacteria which cause the pyrexia are destroyed *in situ*, and, the bacterial toxins being prevented from developing, the inflammatory action ceases.

A. Wulfing & Co., London, Berlin, New York, Cape Town, Sydney, Bombay, Shanghai.

RADIOGEN.

RADIUM PREPARATIONS

KEEP INDEFINITELY and are GUARANTEED of STANDARD STRENGTH

RADIOGEN DRINKING WATER (1000 Mache). As prescribed by Eminent Physicians in England and on the Continent.

The Housing Conditions in Dublin.

The Departmental Committee appointed last November by the Local Government Board for Ireland to inquire into the housing conditions of the Dublin working classes has lost no time in preparing its report,[1] which was presented to Parliament last week. The making of this speed has perhaps brought it about that the report is less full in certain directions than we might have desired, and is probably responsible for a certain lack of arrangement which gives rise to various repetitions. Nevertheless, the report covers well the ground indicated by the terms of reference to the Departmental Committee, and the suggestions made by the committee will form the groundwork of plans for future action. Above all things, the report is outspoken, and no attempt is made by the committee to gloss over the existence of grave abuses in the municipal management of the metropolitan city of Ireland.

For purposes of discussion the document may be divided conveniently into three parts. The first part deals with the present housing condition of the working classes; the second with the powers and activities of the local sanitary and housing authority, the Dublin corporation; and the third embodies the suggestions of the committee for the remedy of the grave troubles whose existence has long been patent, not only to sanitarians and medical men, but to all thoughtful citizens. The conditions under which the working classes in Dublin are housed have been described recently in our columns[2] with some particularity of detail, and in terms that leave no doubt as to their revolting nature. It is not necessary to repeat what we then said, for, indeed, it is all common knowledge now. The general position may be summarised as follows. Some 63 per cent. of the total population of Dublin belong to the working classes, apart from domestic service; and this proportion of the inhabitants live in tenements for the most part of not more than four rooms. About half of this number live in the so-called "tenement houses," each of which accommodates anything from four to eight families. And a little over 20,000 families occupy only one room each. The proportion of the population occupying one-room tenements is thus 22·9 per cent. of the whole, and is higher than can be found anywhere else in Great Britain and Ireland, the urban centre approaching nearest to this sinister situation being the Finsbury district of north London, where 14·8 per cent. of the population inhabit single-roomed tenements. The tenement houses of Dublin are divided by the sanitary staff of the corporation into three groups, the third and worst of which groups is classified under the description "houses unfit for human habitation and incapable of being rendered fit for human habitation." More than one-fourth of the tenement houses of Dublin fall into this group, and 22,701 persons inhabit these houses. Apart from this overcrowding in unsuitable dwellings, the committee find the general sanitation of tenement houses far from satisfactory as regards cleanliness and closet accommodation. The closets are insufficient in number, are common to several families and to both sexes, and are, practically without exception, in a filthy condition. Human excreta are scattered about the yards and on the floors of the closets, and in some cases in the passages of the houses. Our readers can draw the picture for themselves when they recall the factors that go to make it—the careless and poverty-stricken crowds, the seething and disgusting environment. From all this it will be seen that the corporation of Dublin has not used its powers to compel cleanliness in tenement houses with any energy or success, but a sadder moral than this has to be drawn, in the opinion of the Departmental Committee. The paragraphs of the report which deal with the sanitary administration are, indeed, a direct indictment of the entire sanitary administration of Dublin, though it is right to add that one of the committee, Mr. J. F. MacCabe, does not support his colleagues in their blame of the corporation.

The committee, having summarised the sanitary powers of the corporation as regards their housing powers, conclude: "The plea of the corporation in regard to the insufficiency of their powers would have considerably more force were it supported by evidence of a rigid administration of existing powers." This want of a firm administration is declared responsible for the demoralisation of landlords as regards their duties, as well as of the working classes themselves, and has increased the number of inefficient workers in the city. It is shown, indeed, that the most flagrant and persistent breaches of the by-laws have been connived at. A worse thing remains to be told. It is within the powers of the corporation on a certificate from the sanitary staff to grant a rebate of 25 per cent. of the rates due on dwellings suitable for artisans and workmen, and fulfilling certain conditions. This rebate has been granted in many cases on houses classified as "unfit for human habitation," and in more than one instance the landlords receiving this rebate are members of the corporation. Such a state of affairs will certainly receive the closest attention, but the report gives in several places credit to the corporation for securing in recent consigner to treat the goods before shipment; and the alternative, some method of treating the imported raw material on its arrival in this country in such a way as to destroy the infective spores or render them innocuous, has not yet been evolved—in fact, all the processes hitherto suggested, if efficient, have rendered the treated goods valueless from the commercial point of view.

---

[1] Report of the Departmental Committee appointed by the Local Government Board for Ireland to Inquire into the Housing Conditions of the Working Classes in the City of Dublin. London: Wyman and Sons. 1914. Price 1s. 1d.

[2] The Lancet, Nov. 8th, 1913, p. 1334.

Of preventive measures other than those directed primarily to the imported raw material, cleanliness in the persons and habits of those employed in the wool and hide trades is of the first importance. This point has recently been emphasised by the facts elicited during the progress of inquests in Bradford and Southwark respectively. In the former practically a fortnight elapsed between the cessation of work in a wool factory and the onset of the symptoms which terminated in generalised anthrax, but during the whole of that time the same shirt did duty day and night, and its wearer slept with another man who was still employed in the factory from which it was suspected the infection was derived. In the second case, nearly as long an interval occurred between the unloading of a consignment of Siberian hides and the appearance of a charbon on the chin of a casual waterside labourer, and during this interval the man was an inmate of a large common lodging-house under conditions the reverse of cleanly. In both these cases the inference is that the infective spores were carried upon the skin surface or the clothes of either the victims or their intimates for many days before they gained access to the tissues of their final hosts.

Annotations.

"Ne quid nimis."

A COMPLIMENTARY DINNER TO SURGEON-GENERAL GORGAS.

IT is proposed to give a complimentary dinner to Surgeon-General Gorgas, formerly chief of the Sanitary Department at Panama, now Surgeon-General of the U.S. Army, as a mark of professional appreciation of the splendid work achieved by him and by his two assistants, who are included in the invitation. The dinner will be held on Monday, March 23rd, at 8 P.M., and the place will be announced in good time. The proposal is supported by, among others, Sir Thomas Barlow, President of the Royal College of Physicians of London; Sir Rickman Godlee, President of the Royal College of Surgeons of England; Sir Francis H. Champneys, President of the Royal Society of Medicine; Sir David Ferrier, President of the Medical Society; Sir Havelock Charles, President of the Society of Tropical Medicine and Hygiene; Sir William Osler, Regius Professor of Medicine, Oxford; Sir Clifford Allbutt, Regius Professor of Medicine, Cambridge; Surgeon-General Arthur W. May, Director-General of the Naval Medical Service; and Sir W. Launcelot Gubbins, Director-General of the Army Medical Service. Sir Thomas Barlow has consented to take the chair, and it is hoped that the company will be thoroughly representative of the medical profession in London. The price of the dinner ticket (including wine) will be 25s., and as the number of seats is limited application should be made without delay to Mr. J. Y. W. MacAlister, the Royal Society of Medicine, 1, Wimpole-street, Cavendish-square, London, W. Viscount Bryce, until recently our Ambassador to the United States, and Mr. Lewis Harcourt, the Colonial Secretary, have already signified their intention of being present at the dinner.

THE CRAZE FOR HYPODERMIC MEDICATION IN ITALY.

Professor Ferreri, of the University of Rome, seizes the opportunity in a recent number of the *Policlinico*[1] of drawing attention to the alarming proportions this morbid psychic phenomenon has reached in Italy. Hypodermic medication has been elevated to the position of a universal panacea, and the populace is being slowly embalmed by it. Not only are heroic remedies, approved by the official pharmacopœia, introduced under the skin, but all the mysterious specialities, which, thanks to extensive advertisement in the press, are recommended either by medical practitioners, by real or fictitious members of religious orders in the odour of sanctity, or by manufacturers of chemical products on the verge of bankruptcy, are welcomed subcutaneously by a highly credulous public. Why is it, Professor Ferreri asks, that no one has hitherto had the courage to cry out against this monstrous liberty granted to those who are not doctors, and yet incur no responsibility in practising hypodermic medication? He considers that several factors have contributed in inducing this pernicious current of human therapeutics: the ignorance of the populace towards the elementary principles of health, scanty respect for sanitary laws and the acquiescence, not to say pusillanimity, of the medical profession, always at discord and therefore incapable of making its influence felt by the Government and Parliament. In France and Germany the law prosecutes those who, not being doctors, usurp medical functions. In this country, though Professor Ferreri probably does not quite follow the distinction, there is no law against quackery, but only legislation to prevent an unqualified practitioner pretending that he is on the Medical Register. In Italy, however, they allow chemists, druggists, nurses whether trained or not, monks, nuns, and quacks of all kinds not only to give injections of substances in common use or of known composition, but to invent and manufacture them for their own ends. One of the worst results of this strange liberty accorded to those who exploit the functions of medical practitioners is the increasing number of neuropaths who, attracted by the possibility and ease of cure without having to make known their ailments, practise on themselves injections of substances which are often highly dangerous, and in this manner the ranks of the army of morphinomaniacs, cocainomaniacs, and etheromaniacs are largely reinforced. In his own experience Professor Ferreri finds that numbers of patients present themselves for treatment with affections of the ear, nose, and respiratory organs due solely to saturation of the organism with more or less poisonous substances introduced by means of hypodermic medication. To remedy the evil he suggests the passing of a law prohibiting the use of hypodermic syringes except by medical men, and the sale of any speciality for injection which is not manufactured under State control. We may order things slightly better in this country, but nevertheless a perusal of Professor Ferreri's article makes us aware that we too have our grave shortcomings in similar directions.

METROPOLITAN ASYLUMS BOARD: THE POSITION OF ASSISTANT MEDICAL OFFICERS

We are informed that an Association of Medical Officers in the hospitals' service of the Metropolitan Asylums Board has recently been formed. The object of this association is, in general terms, to organise its members for the promotion of their efficiency and the defence of their interests. It is felt by the officers of this branch of the medical service under the Metropolitan Asylums Board that the time has come for a reconsideration of their status. The association, through its executive, will act as a means of communication between the assistant medical officers as a whole and the managers of the Board, and it is hoped that by collective representations, put forward in this way, various grievances which now exist may be remedied. The junior medical officers in fever hospitals and similar institutions undertake very responsible duties, and any endeavour by legitimate means to improve their position and prospects, and so to render the service more attractive, deserves the sympathetic attention of the authorities of these institutions, and should be supported by the medical profession generally. It is well known that the Metropolitan Asylums Board has lately had difficulty in filling junior medical posts, and one of the anomalies of the situation is that locum tenents have been receiving much better remuneration than the experienced officers already in the hospitals' service. The honorary secretary of the new association is Dr. E. G. L. Goffe, North Eastern Hospital, Tottenham, N.

TREATMENT OF EPITHELIOMATA BY SUNLIGHT.

Heliotherapy is much neglected in this country, but considerable attention has been devoted to it of recent years on the continent, particularly in the treatment of various forms of tuberculosis, in which remarkable results have been obtained. The new field of therapeutics opened up by the discovery of the X rays and radium suggests possibilities not yet discovered in the greatest form of radiant energy available on this earth—the sun's rays. In the *New York Medical Journal* of Feb. 7th Dr. H. H. Seelye has recorded several cases of cure of epithelioma by means of sunlight—a method which he claims to be not less efficient than the use of the costly element radium or the X rays. He simply focuses the sun's rays on the growth by means of an ordinary magnifying glass. For a number of years he has found this treatment invariably successful, chiefly in obstinate ulcerative patches on the face that repeatedly shed scabs only to leave a raw and bleeding base, which never heal under ointments, powders, or other local treatment, and recur in ever increasing extent year after year. Such growths are usually of moderate size and are always malignant. Dr. Seelye focuses the clear sunlight on the sore for 10 or 15 minutes at a sitting. If a scab is present he concentrates the rays on it till the patient complains of burning. Then he lengthens the focus so as to cover with the rays an area of an eighth of an inch or more beyond the scab. Every few minutes he induces burning again for a second, not to a degree of cauterisation, and then he applies the rays more mildly. After about ten minutes the scab will look darker. During the next few days it will become more prominent and loosened. The treatment is repeated every day or two till the scab may be easily removed, leaving a raw bleeding ulcer. Then is the time for a powerful application. A few granules of cocaine are first applied. After three or four minutes an exposure so strong as almost to cauterise the ulcer may be borne and alternated with milder applications for about 15 minutes. Milder applications at intervals of three to seven days through the scabs, or immediately after their shedding, will usually complete the cure within three to six weeks. The scabs gradually become thinner and more superficial, and the sore bleeds less after their removal. At last healthy normal skin with scarcely a trace of scar is left. Rarely are more than 8 to 15 applications necessary. The following are examples. A man, aged 80 years, had a sore on the right cheek three-eighths of an inch in diameter, which had been treated without success by several practitioners for years. Scabs fell off or were picked off at intervals, leaving an angry ulcer. After three weeks use of the sun's rays focused as described healthy skin formed over the ulcer and later no sign of the sore or scar remained. Several years have elapsed without recurrence. A woman, aged 80 years, had an epithelioma over the left eyebrow three-quarters of an inch in diameter. It had been treated without avail for several years by various local measures. It always failed to heal and was gradually enlarging. After two weeks' treatment with the sun's rays the ulcer was smaller and shallower and healthy looking. In two more weeks it was completely cured and left no scar. The only case of failure out of seven cases narrated occurred in an old and feeble man. The whole of one cheek was eaten away by a deep, angry, irregular, ulcerating growth of the size of the hand. It was extremely painful and cocaine and morphine were freely used. After half a dozen exposures the ulcer was gradually filling up and there were lessening of secretion and a tendency to heal. But failing strength caused the patient to cease his visits and he took to bed, where he died in a few weeks.

MANGE AS A HUMAN DISEASE.

The study of comparative pathology has opened the eyes of the medical profession to the fact of the close relationship that may exist between all members of the animal kingdom, including man himself, in regard to the extension of various diseases beyond their original sphere of influence. Glanders and anthrax have long been known to be communicable from animal to man. That some intertransmission may exist in tuberculosis has been more lately established. Aphthæ, tapeworm, sleeping sickness and other diseases transmissible from animal to man by biting insects come to mind. The transmission of mange from dogs to human beings was commented on in an illuminating article in the *Veterinary Journal* for November, 1912,[1] and the same journal in its February issue this year publishes a further clear case by Mr. John Buscomb, M.R.C.V.S., in which two Pomeranian puppies suffering from sarcoptic mange infected first the maid who cared for them, and later two neighbours, each of whom took charge of one of the puppies during the absence of their owners. The irritation in the affected human beings was very severe and demanded medical attention. The editor of the *Veterinary Journal* suggests that in the case of a puzzling skin complaint in human beings a consultation with a veterinary *confrère* may help to enlighten the medical attendant. He further insists that the order making mange a notifiable disease should be extended to dogs; and having in view the intimate relations between dogs and the human family we are entirely in accord with him.

THE PANCAKE.

ALTHOUGH there is some obscurity surrounding the origin of the pancake, it is certain in early times to have been associated with more or less hilarious proceedings, whether religious or pagan in origin. One obvious inference is that Shrove Tuesday, or pancake day, was made a festive occasion in view of the approach of the fasting season. The pancake would thus seem to have symbolised a sort of joy-day on which the people meant to have a fling before dietetic restrictions were imposed upon them, and while the full effect of shriving was to be felt. Considered from a physiological point of view, the custom of eating pancakes is commendable; it is a satisfactory fact that they have become popular sweets at other seasons than Quinquagesima, for they are nourishing and digestible food. A review of the ingredients which provide the formula shows at once that the pancake is a singularly complete diet, containing, that is to say, all classes of food materials. It is rich alike in proteins, carbohydrates, fats, and mineral substances, all in an acceptably assimilable form. It is doubtful whether there is a single manufactured or patent food upon the market which can claim such a valuable range of dietetic properties. Apart, moreover, from its dietetic value the pancake possesses an important pharmacology, inasmuch as it is rich in lecithin, which is now known to have a special significance in the processes of nutrition and metabolism.

LARYNGEAL PARALYSIS IN MITRAL DISEASE.

RECOGNITION of paralysis of the recurrent laryngeal nerve in certain cardio-vascular diseases is not of recent date, for as early as 1852 Legroux described a condition of partial aphonia or hoarseness, due to compression of the nerve in a case of aortic aneurysm. Until a few years ago it was thought to take place exclusively in affections of the aorta and some forms of pericarditis of a plastic type, but latterly this symptom has been observed, although not very frequently, also in the course of cardiac valvular disease. For the most part the left recurrent nerve is implicated for well-known anatomical reasons which render it more susceptible to stretching and compression in cases of mitral disease, but interesting cases have been reported by Rossi where the right side was affected, and by Quadrone where both sides were affected. The explanation usually given is compression on the loop of the nerve exercised by an enlarged left auricle, and it is not necessary to insist on the great value of radioscopy in the study and diagnosis of such cases, which are rare, not more than 50 having been published hitherto. In a recent number of the monthly review published in connexion with the Ospedale Maggiore at Milan Dr. D. Tronconi relates a case of ordinary mitral insufficiency which had reached the stage of failing compensation and where a left laryngeal paralysis which developed at the outset of the compensatory failure persisted after this condition had disappeared. The radiograph given of the case confirms the positive and negative aspects of the clinical examination and allows the exclusion of mediastinal or aortic lesions, showing that the laryngeal paralysis is directly and solely dependent on the cardiac valvular lesion. Not only this, but it also proves that the heart, although enlarged, is not displaced, while it is evident that the pulsating prominence of the left auricle goes far to disprove the theory put forward by Kraus that the paralysis in such cases is due to the nerve being stretched in consequence of the displacement downwards of the enlarged heart and vessels.

A SIMPLE AND EFFECTIVE METHOD OF DISINFECTING TYPHOID STOOLS.

IN the *Boston Medical and Surgical Journal* of Jan 8th Dr. H. Linenthal and Mr. H. N. Jones, bacteriologist to the Massachusetts Board of Health, have pointed out the inadequacy of the usual method of disinfecting typhoid stools, which consists in sprinkling over them a little chloride of lime or sulpho-naphthol and promptly depositing them in the water-closet without allowing the disinfectant to mix with them. If the excreta are accessible to flies the danger of the disease being spread is obvious. The bedside disinfection of stools is not such a simple matter as it might appear. The proper utensils are often not available, and the thorough mixing of the stool with the disinfectant and the necessary exposure to its action will in the great majority of cases not be carried out, even when detailed instructions have been given. Dr. A. H. Dotty made experiments with the various disinfectants usually recommended as they are generally employed. He found that at the end of 20 hours' exposure but one eighth of an inch of the fæcal mass was disinfected. Heat—boiling water or steam—is the only effective method of dealing with typhoid stools, but an apparatus for the purpose is not available in households. A method to be of general use must require only such utensils as are available in any household and so simple as to require little skill. A method was devised by Dr. A. M. Kaiser in the Hygienic Institute of Gratz University, and was described by Dr. Prausnitz at the Fifteenth International Congress on Hygiene and Demography held in Washington in September, 1912. It consists in adding enough hot water to cover the stool and then about one-fourth of the entire bulk of quicklime, covering the receptacle and allowing it to stand for two hours. The hydration of the lime generates enough heat to destroy the typhoid bacillus. Dr. Linenthal and Mr. Jones tested this method. They first determined the amount of heat generated and the length of time it is retained. To make the conditions as rigid as possible they used an ordinary tin pail with a loose fitting cover. To a litre of cold water they added from 300 to 400 grammes of ordinary commercial quicklime. They found that the heat generated varied. In some experiments the temperature rose to 80° or even 90° C. in about ten minutes; in others it took 20 to 30 minutes for the temperature to rise to 75°, and a temperature of over 60° was maintained for 1½ hours. In several observations the temperature did not rise above

55°, which was due to the poor quality of the lime, although it came from the same lot as the better lime. If, however, hot water, ranging in temperature from 50° to 65° C., was used in the experiments, the temperature invariably rose to 75° or more in 10 minutes, and in 20 minutes reached 85° and often 90°, and a temperature of over 60° was maintained for 1½ hours or longer. The temperature was maintained for a longer period when an earthen vessel was used than when a tin vessel was. This process therefore generated enough heat to destroy the typhoid or any other organism with the exception of spore bearers. The next question was whether the heat was sufficiently penetrating to destroy the organisms in the centre of the fæcal mass. To determine this capillary tubes containing living typhoid organisms were buried in the centre of the fæcal mass, small lumps of lime, about 400 grammes, were distributed over it, and enough water was added to cover the stool, and the mixture was allowed to stand for 1½ hours. In all these experiments cold water was used. The capillary tubes were then taken out and broken into a bouillon culture. No growth took place. Dr. Linenthal and Mr. Jones conclude that the addition of about a cupful of commercial unslaked lime to a typhoid stool will generate enough heat to kill the typhoid organism. Cold water may often suffice, but it cannot be depended on owing to the varying quality of the lime. Hot water from 50° to 60° C. will always give the desired results. The lime used should be broken up in small pieces and distributed over the stool. This simple and efficacious method should, they consider, take the place of the various methods now recommended.

HYPERPLASIA OF THE MUCOUS MEMBRANE OF THE UPPER RESPIRATORY TRACT.

Two cases of a peculiar hyperplasia affecting the mucous membrane of the upper respiratory tract are described by Dr. A. Logan Turner in the *Journal of Laryngology, Rhinology, and Otology* for February. He has been able to find but four similar cases in the literature; three of these were published by Sir Felix Semon in THE LANCET of Feb. 25th, 1905, and the fourth by Dr. A. Brown Kelly in THE LANCET of April 6th, 1901. The condition is thus obviously one of great rarity. In Dr. Turner's first case, a man, aged 44, in previous good health, was awakened during the night by pain in the throat and dyspnœa. These symptoms progressed, pyrexia followed, and on the fourth day tracheotomy became necessary. Two days later, when Dr. Turner saw him for the first time, the nose and nasopharynx were not abnormal; the uvula and soft palate were œdematous; the epiglottis was red and swollen, and curved backwards so as to form a narrow horseshoe slit; the arytenoids were swollen, and no view of the interior of the larynx could be obtained. There was no history of syphilis, and no benefit was derived from antisyphilitic treatment. After ten days the tracheotomy tube was removed and the patient got along fairly well, though subject to colds with some respiratory trouble, for six years. He then again suffered from laryngeal obstruction, which nearly made a second tracheotomy necessary. Vaccine treatment was then instituted and no further attacks have occurred since. Three and a half years after the second attack of obstruction Dr. Turner found the uvula and soft palate normal, but there was still much infiltration of the epiglottis and arytenoids. His second case was that of a woman, aged 52, who had been under observation for over a year. Her symptoms and signs were similar to those of the first patient, but less severe; tubercle, syphilis, and rhinoscleroma, as well as myxœdema were ruled out of court. Summarising the six cases, Dr. Turner notes that there were four women and two men, ranging in age from 30 to 52. All had enjoyed good health, and showed no evidence of disease elsewhere than in the throat. Absence of ulceration characterised all the cases, and, probably owing to this, pain was not complained of. The vocal cords and the voice were always unaffected. The local conditions vary slightly from time to time, but even after 10 and 14 years neither ulceration nor cicatrisation can be detected. Histologically a great similarity of structure is exhibited; chronic inflammatory changes are present without demonstrable signs of any specific infective disease. No specific micro-organisms have been found. Arsenic, iron, mercury, iodides, and thyroid gland have proved of little value in treatment. Salvarsan has not been tried. Dr. Turner concludes that this is a definite pathological condition of the fauces, pharynx, and larynx which cannot be placed in the category of any recognised disease affecting this part of the body.

THE HOUSE OF THE ROYAL SOCIETY OF MEDICINE.

AT a recent dinner of the Council Club of the Royal Society of Medicine, the President of the Society, Sir Francis Champneys, announced that the Society had now received its title-deeds from Lord Howard de Walden, with a certificate from the Land Registry that the title was a good one. These deeds convey to the Society for 1000 years, save one, the site upon which their new building has been erected. The grant is subject to a moderate ground rent, and for all reasonable purposes the Society has a free hand in dealing with the property. This must be very satisfactory to the Fellows, and particularly to those who have worked hard to establish the Society as a permanent and prosperous institution. It should encourage those who have not already done so to support the building fund, for many Fellows hesitated to do so while the lease, as purchased by the Society, secured a tenure only for 80 years.

TUMOURS OF THE PREFRONTAL REGION OF THE BRAIN.

Dr. L. Newmark, of San Francisco, has published in the *California State Journal of Medicine* for November, 1913, a series of four cases of tumour of the anterior pole of the hemisphere which present certain features of interest from the diagnostic and other points of view. Much diversity of opinion still exists as to the clinical picture produced by tumours in this region. It will be remembered that Dr. A. W. Campbell, in his brilliant investigations on the localisation of cerebral function, came to the conclusion that the importance of the prefrontal region was exaggerated; that on histological grounds (inferiority of nerve cell and fibre supply) it could not be held to share the functional importance of the better developed frontal cortex placed further back; and he expressly declared that "although it may have a future in front of it, at present its evolution, both structural and functional, is incomplete." Dr. J. Shaw Bolton, however, has combated these views, basing his reasoning also on the results of minute histological investigation. He has shown that the prefrontal is the last region of the cerebrum to be evolved, and the first to undergo dissolution in mental decadence. He has apparently demonstrated that it is the chief focus of the subevolution and dissolution of the cerebrum occurring in amentia and dementia, conditions the characteristics of which are decrease, instability, and loss of voluntary control over the processes of cerebral association. The admirable quality of the investigations of such histologists as Campbell and Bolton renders the contradiction of their results the more difficult to explain, so that it is desirable to turn to other evidence for a solution of the problem. There is undoubtedly a persistent, if scarcely justifiable, tendency on the part of physicians to associate intellectual activity with this prefrontal region, a tendency strengthened by a consideration of some recorded cases of frontal tumour that have closely simulated general paralysis. But it must be stated clearly that the experience of the neurologist is, on the whole, definitely against the occurrence of recognisable mental symptoms as characteristic and pathognomonic of tumours of the prefrontal region. Dr. Newmark's experience bears out that of others who are in a position to affirm that "operative interference in this region entails no mental deterioration." That peculiar and well-recognised form of mental change known as "Witzelsucht" or "moria," in which the patient exhibits a sort of fatuous jocularity out of proportion with the gravity of his condition, is not of itself characteristic of prefrontal disease, though not infrequently noted in frontal cases. Dr. Newmark bases his diagnoses on such physical signs as the loss of the sense of smell, local tenderness on pressure over the bone, and earlier and more severe involvement of the optic disc on the affected side. Yet it is the view of many who are in a position to judge that no one of these signs is by itself sufficient. In fact, it may be said that our real knowledge of the exact function or functions of the prefrontal and frontal regions is still in an unsatisfactory condition.

YELLOW FEVER AND INFECTED SHIPS.

THE question of how yellow fever infection may be conveyed from one country to another by means of shipping is one of serious importance to all maritime nations having trade with tropical countries in which the disease is endemic. At the last International Sanitary Congress held at Paris it was agreed by the delegates that a ship can only be regarded as infected from the yellow fever point of view if along with the presence of stegomyiæ an actual case of the disease has occurred on the ship. Some experts of experience maintain, on the other hand, that the occurrence of the malady on board a vessel is not necessary to render it infected, and that from the practical standpoint a ship is dangerous if the insect transmitters of the disease have come on board at an infected port, and have not been destroyed by some effective process of fumigation, even if no person on the vessel is suffering from yellow fever. It is admitted that the disease has at times broken out on board a ship which has been subjected to repeated fumigation. Attention has recently been drawn to this subject by an editorial in the last issued quarterly number, of the *Yellow Fever Bureau Bulletin* (vol. iii., No. 1), in which is also published a short but interesting note by Dr. Juan Guiteras, director of public health in the island of Cuba. This note relates to the occurrence of three cases of yellow fever on the s.s. *Hydra* bound from the Brazilian port of Manaos to Havannah. This vessel while loading at Manaos, a port on the River Amazon, notorious for the number of cases of yellow fever reported there annually, had two of its crew attacked by the disease, one patient dying and the other being left behind in hospital. Four days before sailing the port authorities fumigated the vessel to destroy mosquitoes and 24 hours before sailing the process was repeated at the request of the master of the ship. She sailed from Manaos on June 17th, 1913, calling at Para on the 21st and reaching St. Lucia on the 27th. As the *Hydra* had come from an infected port she was again fumigated according to the regulations. On June 27th the mate complained of illness, but this was not regarded as due to yellow fever infection. On June 30th the vessel arrived at Guantanamo, in Cuba, and reported that the steward had fallen ill on the previous day; his attack was at the time ascribed to malaria, but he grew worse and died on July 5th, the ship having sailed on the previous day for Cienfuegos, where she arrived on July 8th. But meanwhile the boatswain was attacked on July 3rd and died on the 6th. The ship was fumigated for the fourth time at the quarantine station of Cienfuegos and left for Havannah on July 11th, arriving there the same day. The captain of the *Hydra* was attacked by yellow fever at Havannah on July 14th—that is, three days after his arrival. Thus it appears that between June 13th and July 9th this ship was fumigated four times, but notwithstanding this three cases of yellow fever, all ship's officers, occurred on board, and two of them died. The first of these cases was attacked, apparently, 12 days after leaving Manaos. Dr. Guiteras suggests that the respective attacks followed the opening of the holds for the landing of cargo at the ports of call, and that this afforded opportunity for the ship's officers to be bitten by any of the infected stegomyiæ which had escaped destruction by the poisonous vapours of the fumigation. This escape was probably due to the mosquitoes seeking refuge in holes or crevices to which the fumes did not penetrate. It is not improbable that persons employed at the ports of call to unload cargo might also have been bitten by these mosquitoes, and a local focus of the infection might have developed on shore. There appears to be some reason for thinking that possibly the routine fumigations performed at certain ports are not effective and that perhaps it is not so easy after all to destroy stegomyiæ completely on a ship which has its cargo *in situ* at the time of fumigation.

Dr. H. H. Tooth, Dr. Risien Russell, Dr. J. S. Collier, and Dr. S. A. K. Wilson have been elected corresponding foreign members of the Société de Neurologie of Paris.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—The annual general meeting of the guild will be held on Tuesday, March 3rd, at University College Hospital Medical School, Gower-street, W.C., at 3 P.M., the Viscountess Bryce in the chair. The business includes presentation of the annual report and election of the executive committee. The hospital will be open to members of the guild and their friends by the kind permission of the general committee.

MEDICINE AND THE LAW.

Dean v. *Rubian Art Pottery, Limited.*

IN a recent appeal from the judge of the Staffordshire county court some interesting points were raised with regard to the liability of employers under the Workmen's Compensation Act in cases of industrial poisoning. Dean, a potter, had worked in March and April, 1913, for the Rubian Art Pottery, Limited, in a process in which lead was used, and he died from lead poisoning on May 15th. The employers mentioned, when a claim was made against them by the dependents, added as respondents previous employers for whom the deceased had worked in lead processes more than 12 months before his death. When in the service of these Dean had apparently contracted lead poisoning, and there appears to have been no doubt that he suffered from it for some time and that it hastened his death. The county court judge had held that there was no evidence that the death had been accelerated by the employment by the Rubian Art Pottery Company, and that the employment by the additional respondents had been more than 12 months before death, so that neither was liable. The dependents appealed and the Court of Appeal upheld in effect the decision of the county court judge, holding in particular that there was nothing in the Workmen's Compensation Act, 1906, Section 8, under which the claim was made, to exempt the claimant from proving that in fact the "accident" arose out of and in the course of the employment; and also that April 19th (the last date of working for the respondents) was not "at or immediately before" May 15th, the date of death, so as to raise a presumption in the applicants' favour.

Bailey v. *The Insurance Section of the Coöperative Wholesale Society, Limited.*

This was an appeal from a county court judge sitting at Leicester. The plaintiff, a member of an Approved Society, claimed sickness benefit upon a medical certificate which stated that she was "suffering from debility and unable to work." The defendants declined to pay on the ground that no specific disease was mentioned, and objected that the county court had no jurisdiction, the case being one for decision under Section 67 of the National Insurance Act. The plaintiff claimed that the decision in Heard *v.* Pickthorne was in her favour on the question of jurisdiction, and the deputy county court judge, accepting this contention, tried the case and decided in the plaintiff's favour. The Divisional Court, upon appeal, were of opinion that the case was distinguishable from that of Heard *v.* Pickthorne, and that consequently the question was one to be determined according to the rules of the society and that the county court had no jurisdiction.

Keats v. *the "Weekly Budget," Limited: Keats* v. *Conolly and Others.*

In January Mr. W. J. C. Keats successfully sued the *Weekly Budget* for libel, recovering £100 damages. A second action brought by the same gentleman as plaintiff has since been tried by the Lord Chief Justice and a special jury with a similar result (£100 damages), the principal defendant being Mr. J. C. Conolly, editor of the *Dulwich, Peckham, and Camberwell Post.* Both actions arose out of comments upon the same series of acts, allegations being made to the effect that Mr. Keats inflicted brutal chastisement upon sick boys in the Camberwell Infirmary by flogging them with a whip. In the case against Mr. Conolly one of the articles complained of was headed, "Guardians; Dr. Keats's Cat-of-five-tails; Flogging Children in the Infirmary." Another was a copy of a letter which appeared in *John Bull*, and was headed "Flogging Sick Lads in an Infirmary." The articles referred in some detail to the ages of the boys chastised, and gave a highly coloured version of the nature of the chastisement, which consisted, as was not denied by Mr. Keats, in whipping them on the buttocks with five strands of moderately thick string. The whole matter had been brought before the guardians by the Countess de Lormet, a member of the board. Mr. Keats explained in his evidence that the refractory boys were not sick, but convalescent, and that their conduct to nurses and generally their refusal to yield to discipline rendered the conduct of the infirmary impossible without chastisement, which in no case was of a character that could reasonably be complained of as brutal or excessive. He pointed out that a refractory boy could be turned out of a voluntary hospital, but that this could not be done in a Poor-law infirmary. He had been recently awarded an increase of salary by the board of guardians. Corroborative evidence as to the boys' conduct and the punishment was given by a nursing sister. Mr. Keats is to be congratulated upon the successful issue of the actions forced upon him by attacks which left him no alternative but to defend his character from cruel charges. These if true would have proved him unworthy to hold his appointment, and the London and Counties Medical Protection Society, who through their solicitors, Messrs. Le Brasseur and Oakley, conducted his cases on his behalf, may also be congratulated upon the successful issues achieved. How the lady guardian who objected to Mr. Keats's action or the editor who attacked him would maintain discipline among the wilder spirits in Camberwell Infirmary by gentler means than those adopted by Mr. Keats is a matter which they may be able to explain, but to allow them to give a practical example of their methods would probably be a dangerous experiment. It must be remembered that lack of discipline among a few of the members of a ward, where some are weaker, more helpless, and more ill than they, is likely to inflict considerably more mental and physical suffering upon the majority than Mr. Keats imposed upon two or three who by their acts deserved it.

A Medical Witness's Expenses.

At the Widnes county court recently a medical man sued a solicitor for 14*s.* 6*d.* balance of a fee for services rendered. The plaintiff had given evidence in a case in which the defendant was solicitor for the successful party and had been allowed £20 for witnesses' expenses. Of this sum the defendant had paid 10*s.* to the plaintiff, and denied all further liability for the balance, which included railway fares. His honour found that there had been some undertaking to pay and that the medical man was entitled to a reasonable fee. He awarded him 10*s.* 6*d.* in addition to the 10*s.* already paid.

Soda and Milk.

A curious point was raised and may lead to an appeal in a case in which a confectioner was summoned at Bow-street police court for refusing to sell for analysis a sample of milk exposed for sale in his shop. It was stated that it has become a custom for confectioners to sell soda and milk, and to refuse to sell milk when asked for it. In the case in question a jug was on the counter labeled "Pure milk," but the manager declined to sell any. The summons was dismissed, but it was intimated by Mr. Rotton, who prosecuted, that the prosecutors, the Westminster City Council, might appeal upon the point of law involved. It is clearly desirable that they should do so if they are advised that they have a prospect of success. As Mr. Rotton submitted to the magistrate, the duty of milk inspection will be difficult to carry out efficiently if a defendant can prevent a sample from being taken in the manner described. There was nothing in this instance to show that sales were not genuinely confined to milk diluted with soda-water, but even in that case the customer should be protected against adulterated milk being used. In the case of those who sell milk without soda-water, it should not be possible for them to prevent its purity from being tested by alleging a trade in "milk and soda."

THE HOME TREATMENT OF PULMONARY TUBERCULOSIS.

THE New York Association for Improving the Condition of the Poor began nearly two years ago a most interesting experiment in the treatment of tuberculosis among the poor, and now issues a valuable report upon the progress of the essay and the lessons of the first completed year of working.

An investigation made some time ago by the association, which is entirely philanthropic in constitution, showed that 55 per cent. of the widows receiving assistance from the association were widows because the breadwinner had died from tuberculosis. To relieve the poverty and disease of such families a scheme was planned which resulted in the establishment of what is termed a "home hospital"—in other words, a block of workmen's dwellings was hired and filled with families one or more members of which were tuberculous. A woman superintendent was installed and physicians visited regularly. Hygiene was rigorously attended to, the children were provided with a roof playground, and the tuberculous members of the families received adequate treatment. Let it be added that the experiment was not designed to supplant sanatorium treatment, but to ascertain whether it was possible in a crowded city to check the spread of tuberculosis. The waiting lists of such sanatoriums as are available for the poor of New York are so over-full that for thousands of tuberculous poor spreading contagion in dark and dirty tenements it was felt that it was a case of home treatment or nothing. The agencies already in operation—dispensaries, hospitals, and clinics of various kinds—were concerned with individual cases rather than with families of which there were tuberculous members. These agencies there was no intention to supplant; the field was found to be so large that the association felt able to supplement them by attending especially to the social and family side of the tuberculosis problem.

In selecting families for admission to the home hospital preference was given: first, to families in which tuberculosis and poverty were more or less incipient; secondly, to those believed to possess sufficient intelligence to coöperate in the experiment; thirdly, to those in which dependency was due to tuberculosis in the wage-earner; fourthly, to those in which tuberculosis of the mother rendered it inadvisable for family life to continue in existing conditions; and in general to poor families made dependent by tuberculosis, in which the disease was not more than moderately advanced. The care bestowed included regular physical examination of the actual patients, sputum tests, segregation of the advanced cases, outdoor life on balcony, roof, or the adjacent park, complete rest when necessary, graduated exercise, nursing, and medicines. Instruction was also given regularly in cooking, sewing, care of infants, cleanliness, hygiene, and sanitation.

The results of the first year's work were so encouraging that the association decided to extend the scale of its operations by doubling the capacity of the home hospital. The report deals fully with the statistics of that year, and the results disclosed are wonderfully good. Twenty-seven families, containing 135 individuals, were admitted. Seventy-nine of these persons were patients or suspects. No new cases developed among the non-infected members of these families, and only one death was recorded among the tuberculous. 61 per cent. of the adult patients who followed directions and were at least six months under treatment were apparently cured; in 22 per cent. the disease was arrested; and 11 per cent. were much improved. Among the children the results were also highly satisfactory; most of them were undeveloped and puny on admission, but left the home hospital healthy and strong. The cost of the experiment came to nearly £7000; and it has also to be borne in mind that much unremunerated labour was given by doctors and others; the average stay of each family was 233 days. Still, even then, the cost compares favourably with that of sanatorium treatment for the 79 tuberculous; and, in addition, the non-tuberculous members of the families were supported and saved from the ravages of the disease. When it is remembered that these results were secured in the first year of the experiment, among patients most of whom would otherwise have received no treatment, with the family unit preserved, and in the heart of New York, there seems to be good ground for believing, as the association does, that a real contribution is being made to the problem of tuberculosis combined with poverty and to the control of these two allied enemies of health in the congested districts of large urban communities.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the seventeenth meeting of the Royal Commission on Venereal Diseases evidence was given by Dr. S. Coupland and Dr. C. Hubert Bond, Commissioners in Lunacy.

The witnesses stated that since 1876 the figures published by the Lunacy Commissioners showed that there had been a gradual rise in the recorded proportion of syphilitics admitted to asylums, but it could not be inferred that this increase denoted an increasing incidence in actual prevalence of syphilis; the increase shown in the figures might mean nothing beyond more thorough investigation and observation in respect to this particular. Throughout the whole period there has been a preponderance in the proportion of male cases in the private over that in the pauper class, and generally a similar but less markedly higher incidence in females of the pauper than in those of the private class. For the period 1908–12 the figures showed that of the male admissions 11·8 per cent. of the private cases and 8·7 per cent. of the pauper cases were syphilitics; for females the corresponding figures were 0·7 per cent. among private and 1·4 per cent. among pauper patients. Much variation in the degree of incidence appears in the inmates of different asylums, but speaking generally those institutions that receive inmates from industrial districts show higher ratios than those which deal mainly with an agricultural and rural community. About 60 per cent. of the cases known to be syphilitic admitted in the period 1908–12 were general paralytics.

At the eighteenth meeting evidence was given by Sir Thomas Barlow, Bart., K.C.V.O., President of the Royal College of Physicians of London.

Sir Thomas Barlow dealt first with the importance of congenital syphilis and its effect as a hindrance to the birth-rate and to healthy development. He described how syphilis frequently manifests itself in the offspring of a woman affected by the disease in producing first one or more miscarriages and afterwards children apparently healthy at birth, but sooner or later suffering from various affections. He stated that the life of these children at school, especially amongst the humbler classes, was most unpromising, and that many of them became perfectly useless members of society. He also drew attention to the fact that syphilitic infants are notably liable to convulsions, and that in these children the convulsions may inaugurate very serious diseases of the brain.

Sir Thomas Barlow next gave illustrations of the latency of the disease, and pointed out the importance of realising how very widespread the damage caused by congenital syphilis may be, and that causes, for which no explanation can be given, may revive manifestations of congenital syphilis in many different situations. He emphasised the importance in cases of this kind of maintaining continuous supervision of both parents and families. He considered that the ideal method of treatment and prophylaxis would be, given a syphilitic infant, that both parents should be under medical supervision and medical inspection at frequent intervals, and other children of the family born subsequently should be inspected also at frequent intervals, and that this surveillance should continue for several years.

Sir Thomas Barlow said it was very difficult to estimate whether venereal diseases were less prevalent at the present time than formerly. He thought, however, that there was a general improvement in the morality of the population, and that the higher standard obtaining ought in time to produce less prevalence of the diseases. He thought it very hopeful for any educational crusade that might arise out of the work of the Commission, as the public mind was in a state of most promising preparedness to receive admonition and to recognise the moral obligation of these things being dealt with. He was of opinion that special education or instruction on these subjects was very desirable. It might be begun possibly in the public schools, but certainly in the university period. More generally he thought that instruction should be given directly young people were sent to work. In any educational measures he would urge that medical practitioners, and if possible family doctors, should be the backbone of the organisation. Besides the family doctor he thought that for young children the person to impart knowledge was the mother. He believed that something had been done in Western Canada in the way of special teaching to women of sexual conditions, and this teaching had been of a wholesome character and had been given without any offence whatever.

Sir Thomas Barlow was not in favour of notification of venereal diseases, and it was his opinion that there was much more to hope from general enlightenment and education. Apart from education, he considered that what was required practically was the provision of facilities for effective and complete treatment in the early stages and the improvement of those facilities to the utmost. He also advocated strongly the subsidisation by the Government of pathological research.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8453 births and 5203 deaths were registered during the week ended Saturday, Feb. 21st. The annual rate of mortality in these towns, which had been 18·4, 16·5, and 15·6 per 1000 in the three preceding weeks, further declined to 15·0 per 1000 in the week under [illegible] weeks of the current quarter the [illegible] these towns averaged 17·0 per [illegible] rate recorded in London during the same period. Among the several towns the death-rate last week ranged from 5·3 in Hornsey, 5·7 in Ilford, 6·2 in [illegible] 6·7 in Oxford, and 7·9 in [illegible] id in South Shields, 21·0 [illegible] and in Swansea, 27·3 in Bury, and 27·5 in Burnley.

The 5203 deaths from all causes were 227 fewer than the [illegible] included 397 which were [illegible] ist [illegible] 97 [illegible] h, [illegible] 33 [illegible] om [illegible] es last week was equal to 1·1, against 1·1 and 1·2 per 1000 in the two preceding weeks. The deaths attributed to measles, which had been 79, 64, and 89 in the [illegible] rose to 115 last week, [illegible] al death-rates of 2·3 in [illegible] 5·2 in Burnley, and 5·6 in [illegible] to whooping-cough, which [illegible] to 129 in the six preceding [illegible] k; the highest death-rates [illegible] nsea, 1·7 in Rochdale and in Newport (Mon.), and 1·8 in Great Yarmouth and in Bury. The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 93, 66, and 68 in the three preceding weeks, further rose to 70 last week, and included 27 in London and 5 in Manchester. The deaths attributed to diphtheria, which had been 85, 70, and 64 in the three preceding weeks, further fell to 52 last week, of which 21 were recorded in London and its suburban districts and 3 in Norwich. The deaths referred to scarlet fever, which had been 29, 38, and 37 in the three preceding weeks, declined to 33 last week, and included 4 in London, 4 in Liverpool, and 3 in Birmingham. The fatal cases of enteric fever, which had been 21, 21, and 14 in the three preceding weeks, rose to 17 last week, of which 5 occurred in London, 3 in Sheffield, and 2 in Birmingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3599, 3554, and 3537 at the end of the three [illegible] day last; [illegible] 460, 379, [illegible] ospitals also contained on Saturday last 1176 cases of diphtheria, 307 of whooping-cough, 93 of measles, 81 of enteric fever, and 1 of small-pox. The 1229 deaths from all causes were 22 [illegible] in the corresponding week of last year.

Of the 5203 deaths from all causes in the 97 towns, 206 were attributed to various forms of violence, and 426 were the subject of coroners' inquests. The causes of 37, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, and in 68 other smaller towns. Of the 37 uncertified causes of death last week 7 were recorded in Birmingham, 5 in Liverpool, 3 in South Shields, 2 in Rotherham, and 2 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In [illegible] tion [illegible] 1167 [illegible] week [illegible] mort. [illegible] these Scotch towns averaged 19·0, against a corresponding rate of 17·0 per 1000 in the 97 large English towns. Among [illegible] from measles, 16 from infantile diarrhœal diseases, 14 from diphtheria, 6 from scarlet fever, 3 from whooping-cough, and 1 from enteric fever, but not one from small-pox. These 82 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 1·1 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 48, 34, and 41 in the three preceding weeks, were 42 last week, of which 25 occurred in Glasgow, 10 in Edinburgh, and [illegible] infants (under 2 years) referre[illegible] which had been 12, 7, and [illegible] weeks, rose to 16 last week, a[illegible] Dundee, 2 in Coatbridge, and 2 [illegible] of diphtheria, which had been [illegible] preceding weeks, rose to 14 last week, and included 4 in Glasgow, 4 in Dundee, and 4 in Aberdeen. The deaths attributed to scarlet fever, which had been 10, 6, and 7 in the three preceding weeks, were 6 last week, of which 2 occurred in Glasgow and 2 in Kirkcaldy. The deaths referred to whooping-cough, which had averaged 6 in the earlier weeks of the quarter, declined to 3 last week, which were recorded in Glasgow, Coatbridge, and Kirkcaldy respectively. The [illegible]

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 622 births and 441 deaths were registered during the week ended Saturday, Feb. 21st. The annual rate of mortality in these towns, which had been 24·0, 21·9, and 18·9 per 1000 in the three preceding weeks, rose to 19·1 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these Irish towns averaged 22·1 per 1000; in the 97 large English towns the corresponding rate did not exceed 17·0, while in the 16 Scotch towns it was equal to 19·0 per 1000. The annual death-rate last week was equal to 20·7 in Dublin (against 14·2 in London and 15·6 in Glasgow), 18·8 in Belfast, 19·0 in Cork, 10·1 in Londonderry, 23·0 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 17·8 per 1000.

The 441 deaths from all causes were 4 in excess of the number in the previous week, and included 26 which were referred to the principal epidemic diseases, against 37 and 35 in the two preceding weeks. Of these 26 deaths, 10 resulted from infantile diarrhœal diseases, 6 from whooping-cough, 4 from diphtheria, 3 from measles, and 3 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases last week did not exceed 1·1 per 1000, which coincided with that in the 97 large English towns, while in the 16 Scotch towns the corresponding rate reached 1·9 per 1000. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 6, 7, and 8 in the three preceding weeks, further rose to 10 last week, of which 4 were recorded in Dublin and 2 in Tralee. The deaths referred to whooping-cough, which had been 7, 6, and 9 in the three preceding weeks, fell to 6 last week, and included 3 in Dublin. The 4 fatal cases of diphtheria, 2 of which occurred in Belfast, were slightly in excess of the average in the earlier weeks of the quarter. The deaths attributed to scarlet fever, which had been 5, 10, and 9 in the three preceding weeks, declined to 3 last week, and were recorded in Belfast, Cork, and Limerick respectively. The deaths referred to measles, which had averaged 6 in the earlier weeks of the quarter, fell to 3 last week and were all registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 157, 132, and 99 in the three preceding weeks, further fell to 91 in the week under notice. Of the 441 deaths from all causes, 129, or 29 per cent., occurred in public institutions, and 8 resulted from various forms of violence. The causes of 17, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Morris Charles Langford has been placed on the Retired List at his own request (dated Feb. 19th, 1914).

The following appointments have been notified:—Staff-Surgeons: A. A. Forrester to the *Implacable;* L. F. Cope to the *Victory*, for R.N. Barracks, temporary; and L. Warren to the *Halcyon*, additional, for the *Speedy*, on recommissioning. Surgeon: A. B. Clark to the *Halcyon*, additional, for the *Seagull*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel William Turner is placed on retired pay (dated Feb. 25th, 1914).

Major Samuel H. Withers to be Lieutenant-Colonel, vice W. Turner (dated Feb. 25th, 1914).

The undermentioned to be Lieutenants (on probation) (dated Jan. 30th, 1914):—Lieutenant Treffry Owen Thompson, from the Royal Army Medical Corps Special Reserve; Stanley James Linzell, Lewis Rudall Shore, John Galbraith Gill, John William Cotter Stubbs, Sidney Martin Hattersley, David Wylie Rintoul, and Allan Watson; Lieutenant Norman Veitch Lothian, from the Royal Army Medical Corps Special Reserve; Thomas Francis Pennefather Breen; Lieutenant John FitzGerald Gwynne, from the 3rd West Riding Field Ambulance, Royal Army Medical Corps (Territorial Force); and Arthur John Alexander Menzies.

The undermentioned Lieutenants are seconded under the provisions of Article 343 Royal Warrant for Pay and Promotion, 1913:—Bernard Woodhouse (dated Jan. 1st, 1914); Treffry O. Thompson, Stanley J. Linzell, and Lewis R. Shore (dated Jan. 30th, 1914).

Colonel C. E. Nichol, D.S.O., has been selected for appointment as Assistant Director of Medical Services to the Jubbulpore and Jhansi Brigades, vice Colonel T. J. R. Lucas, retired. Colonel W. W. Pike, D.S.O., has been selected for appointment as Assistant Director of Medical Services to the Abbottabad and Sialkot Brigades, vice Colonel R. Kirkpatrick, C.M.G.

Lieutenant-Colonel C. Cooper Reilly, in charge of the Military Hospital at Calcutta, has been granted six months' general leave of absence home from India. Lieutenant-Colonel W. Turner has been selected for appointment as Deputy Assistant Director of Medical Services to the Welsh Division, vice Lieutenant-Colonel C. A. Young, whose tenure will expire on April 1st. [illegible] has taken over charge of the M[illegible] Lieutenant-Colonel H. J. Fletcher has been granted six months' general leave of absence home from India. Lieutenant-Colonel G. G. Adams has been appointed to officiate as Assistant Director of Medical Services to the Secunderabad Brigade. Lieutenant-Colonel R. Holyoake has been appointed Senior Medical Officer on board the transport s.s. *Plassy*, which left Southampton for Bombay on Feb. 20th.

Major H. E. J. A. Howley, in charge of the Military Hospital at Dinapore Cantonment, has been granted six months' general leave of absence home from India. Major J. T. Johnson has been selected for appointment as Deputy Assistant Director of Medical Services (Sanitary) to the Eighth (Lucknow) Division. Major L. L. G. Thorpe has taken up duty in Madras Presidency. Major C. J. O'Gorman, D.S.O., has been appointed to hold charge of the civil medical duties of the Barrackpore Division, vice Lieutenant-Colonel F. J. Morgan, placed under orders to proceed to join the Home Establishment. Major C. E. Pollock has embarked for a tour of duty in the Sierra Leone Protectorate. Major P. S. Lelean, specialist sanitary officer to the North of Thames Area of the Eastern Command, has been selected for appointment as Assistant Professor of Military Hygiene at the Royal Army Medical College, vice Major H. B. Fawcus. Major H. K. Palmer, on arrival home from India, tour expired, has been appointed to the Military Hospital at Cosham. Major H. S. Roch has arrived home on leave of absence from the Military Hospital at Pretoria. Major J. Poe has taken up duty at the Military Hospital at Shorncliffe. Major B. Watts has been appointed to the London District on arrival home from Meerut Cantonment. Major S. de C. O'Grady has been transferred to the Aldershot Command from the Tower of London. Major H. Herrick has been appointed to hold charge of the Military Hospital at Holywood on return home from Naini Tal Cantonment. Major M. MacG. Rattray has been transferred from the Military Hospital at Brighton to Shorncliffe. Major A. D. Waring has taken up duty at Gosport. Major J. Matthews has been appointed to hold charge of the Military Hospital at Sheffield.

Captain W. W. Browne has been appointed Specialist in the Prevention of Disease to the Ahmednagar Brigade and placed in charge of the Bacteriological Research Laboratory at Headquarters, Ahmednagar Cantonment. Captain L. Cotterill has taken up duty in India on transfer from the Aldershot Command. Captain H. St. M. Carter has taken up duty in the Aldershot Command. Captain H. M. J. Perry, specialist in bacteriology to the Devonport District, has been transferred to the London District, and appointed for duty at the Military Hospital, Rochester-row. Captain R. E. Humfrey has relinquished duty at Queenstown, and embarked for a tour of service in India. Captain M. B. H. Ritchie has arrived home for duty from the Military Hospital at Mhow Cantonment. Captain M. J. Cromie has been transferred from Maidstone to the Military Hospital at Chatham. Captain L. G. Gibson has been appointed for duty on board the transport s.s. *Rohilla* leaving Karachi for Southampton on March 19th with tour-expired troops and invalids. Captain A. C. Amy, who has arrived home for duty from the Military Hospital at Agra Cantonment, tour expired, has been appointed to the Western Command. Captain W. Mitchell has been transferred from the Military Hospital at Subathu to Ambala Cantonment. Captain J. R. Foster has been transferred to the Home Establishment from India. Captain F. Casement has been appointed Specialist in Dermatology and Venereal Diseases to the Eighth (Lucknow) Division. Captain M. J. Lochrin has arrived home for duty from Bangalore Cantonment, tour expired. Captain E. B. Lathbury has been transferred from the Military Hospital at Ranikhet to Bareilly Cantonment. Captain F. C. Lambert has embarked for a tour of service in India. Captain E. C. Phelan has taken up duty at Barrackpore. Captain R. G. H. Tate, on arrival home from the Military Hospital at Lahore, has been appointed to the Irish Command. Captain G. F. Dawson has been appointed Specialist in Electrical Science and Radiography to the Seventh (Meerut) Division. Captain C. H. Denyer has been transferred from the Military Hospital at Landoor to Agra Cantonment. Captain T. H. Scott has been appointed to the Northern Command. Captain A. W. Howlett has joined the Aldershot Command. Captain F. J. Stuart has been appointed Specialist in Dermatology and Venereal Diseases to the Seventh (Meerut) Division. Captain R. D. O'Connor has been transferred from the Military Hospital at Murree to Multan Cantonment. Captain E. M. Middleton has been appointed to the Eastern Command. Captain A. Shepperd has been transferred from the Military Hospital at Agra Cantonment to Burma for a tour of duty at Maymyo.

[illegible] has been transferred from the [illegible] to Jullundur Cantonment. [illegible] ve embarked for a tour of [illegible], S. J. Higgins, G. A. Blake, L Dunbar, H. E. Panton, R. Davidson, and A. G. Biggam. Lieutenant W. B. Laird has been appointed to the Military Hospital at Bangalore Cantonment Lieutenant H. J. G. Wells has embarked for a tour of service in India Lieutenant E. C. Deane has been appointed to the Military Hospital at Lucknow Cantonment

An examination for 12 or more commissions in the Royal Army Medical Corps will be [illegible] to compete should be made [illegible] later than nine days before [illegible]

INDIAN MEDICAL SERVICE.

Colonel H. Hendley, Deputy Director of Medical Services [illegible] rmy in India Colonel C J. [illegible] eneral of Civil Hospitals in the [illegible]

Lieutenant Colonel and Brevet Colonel B Seton, Deputy Director General, has been granted leave of absence home from India. Lieutenant Colonel R. H. Elliott has been granted an extension of leave of absence home from India on medical certificate for six months The services of Lieutenant Colonel E Jennings, on his return from leave of absence, have been replaced at the disposal of the Commander-in Chief in India. Lieutenant-Colonel T. E Dyson has been appointed to officiate as Assistant Director of Medical Services to [illegible] Lieutenant Colonel [illegible] has taken up duty [illegible] State. Lieutenant [illegible] appointed Superintendent of the Central Prison at Allahabad, and to hold officiating medical charge of the 121st Regiment of Pioneers

Major J. McPherson has arrived home on leave of absence from India. Major E. E Waters has been appointed to officiate as Civil Surgeon at Howrah during the absence on leave of Lieutenant-Colonel A. H Nott. Major A. E. J. Lister has been appointed Professor of Physiology on the staff of King George's Medical College at Lucknow. Major S. P. James, Assistant Director-General Sanitary Branch, [illegible] home [illegible] ntral [illegible] inted [illegible] India for a total period of two years. Major R. L. Lloyd, professor of biology at the Medical College, Calcutta, has been confirmed in that appointment

Captain S. H. L. Abbott has been appointed to officiate as Superintendent of the Jail at Ferozepore. Captain R. J Bradley has taken over medical charge of the 1st Gurkha Regiment Captain J. W. H. Babington has been transferred from Rawal Pindi to Madras Presidency for temporary duty in the Civil Medical Department Captain G. T. Burke has arrived home on leave of absence from India. Captain J. W. H. Robinson has been temporarily appointed to the Civil Medical Department in Madras Presidency Captain E. S Phipson has been appointed for temporary duty in the Sanitary Department of the Government of Burma. Captain G. McG. Millar has arrived home on leave of absence from India.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Rowland B Campion is confirmed in his rank

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Highland Field Ambulance, Royal Army Medical Corps: Alastair Robertson Grant to be Lieutenant (dated Jan 28th, 1914).

1st Home Counties Field Ambulance, Royal Army Medical Corps: Charles Killick to be Lieutenant (dated Feb 21st, 1914).

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Captain William F Munro ceases to serve with No 18 Field Ambulance, Royal Army Medical Corps, Special Reserve, and is restored to the establishment (dated Feb 21st, 1914)

2nd South Midland Field Ambulance, *Royal Army Medical* Corps: Major George W. Craig to be Lieutenant-Colonel [illegible] l, Royal Army Medical [illegible] ms to be Captain, whose [illegible] bilisation (dated Jan. 1st, 1914).

1st Western General Hospital, Royal Army Medical Corps: Lieutenant-Colonel Nathan Raw, whose retirement was announced in the *London Gazette* of August 19th, 1913, is granted permission to retain his rank and to wear the prescribed uniform.

Attached to Units [illegible] John Goss resigns h [illegible]

Supernumerary for [illegible] Lieutenant Andrew [illegible] University Contingent, Senior Division, Officers Training Corps) resigns his commission (dated Jan 29th, 1914).

DEATHS IN THE SERVICES.

Fleet Surgeon Alfred Hutton Jeremy, R.N., of the *Impregnable*, recently in London He entered the Navy in 1893, and was promoted to the rank of staff surgeon in 1901. He was staff surgeon of the *Fox* during the Hodeida and Henjam incidents, 1905 and 1906

MEDICAL INSPECTION OF SCHOOL CHILDREN.—In reply to a recent deputation from the Parliamentary committee of the last Trade Union Congress, the President of the Board of Education declared that he had made every effort to obtain an adequate grant from the State for the medical inspection of school children His department was bringing pressure to bear upon local authorities in order to secure that every child was inspected medically at least thrice during the school period, and that where necessary inspection was followed by treatment.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—This society held its annual dinner at Hotel Great Central on Feb 19th The chair was occupied by Dr F. S Palmer, who was supported, besides those whose names occur below, by Sir David Ferrier, Dr. Phineas Abraham, and Professor T. B Hyslop. Mr. Bishop Harman, in proposing the toast of "The Imperial Forces," paid a cordial tribute to the work done by the forces in South Africa, and gave many interesting details of what he had himself observed there Sir James Porter, responding for the Navy, deprecated the pessimism of old gentlemen who wandered about clubland complaining that the service was going to the dogs Colonel Edmund M. Wilson, replying for the military forces, urged the popularisation of the army, the inculcation of the idea that it was not only an obligation but an honour for every able-bodied man to render some service to his country. The medical profession, he said, could do this, for it had led the way the medical part of the Territorial service was full and up to date The President, in proposing "The Society," said that it owed its origin largely to the late Mr. C. B Keetley, of whom he spoke feelingly. Of the 145 original members of the West London Medico-Chirurgical Society 29 were still living and several were present. There were now 575 members, and their meetings showed an average attendance of 42 He expressed their pleasure at having the coming Cavendish lecturer with them. Colonel T H Hendley, in reply, spoke of the extent to which service men joined the society and availed themselves of the opportunities afforded them by the West London Hospital. The event of the evening was the presentation by the President to Professor Arthur Keith of the society's triennial gold medal, which had been established by Dr Phineas Abraham He spoke of Professor Keith's career, scientific achievements, and modesty, and then presented the medal in recognition of Professor Keith's valuable services to science and to the profession of medicine Professor Keith, in responding, modestly deprecated any special claim to the honour. It was his great good fortune to be called first not to a university but to a large medical school—the London Hospital—where he learnt to realise the danger of anatomy and medicine turning their backs upon one another. It had been his endeavour to make [illegible] the Royal Society of Medicine, and Dr F. W. Mott, their Cavendish lecturer for 1914. Sir Francis Champneys, in replying, spoke of the satisfactory progress of the Royal Society of Medicine, and Dr. Mott caused great amusement by referring to Professor Keith's struggles over the Piltdown skull, and reminding his hearers of what happened, according to Bret Harte, in an [illegible] toric remains The proceedi [illegible], of "The Chairman," propose [illegible]

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(By our Special Commissioner.)

(Continued from p. 568.)

XXXVIII.—London: The Persistence of Dislike to the Act.

We have seen that at first the London medical men who would not go on the panel were for the most part isolated, unorganised, helpless. What with the divided attitude of the British Medical Association and the admittance of panel doctors into the National Medical Guild, this feeling of hopelessness was somewhat intensified. In the provinces there was a better show of organisation in those places where any effective opposition was taking place, and we have seen that in Edinburgh the Scottish Medical Guild was emphatically opposed to the contract system and to the Act.

The National Medical Union.

The opinion grew stronger and stronger that for the purpose of organisation the members of an association must be all of the same opinion. Even if it be a trade union, all the members must be either for or against the panel.

All this led up to the formation of an association, which was ultimately called the National Medical Union. The first object was to group together the small local London societies and then federate them with all similar bodies existing in other parts of the kingdom. This was finally achieved at a representative meeting held at the Waldorf Hotel on Nov. 31st, 1913. The national character of the new organisation was illustrated by the fact that Professor William Russell, of Edinburgh, and Mr. G. A. Wright, of Manchester, were elected presidents, and Dr. John Playfair, president of the Edinburgh Medical Guild, was elected vice-president. For secretaries Dr. R. Carswell, of Wandsworth, and Mr. E. Arthur Dorrell, secretary of the London Medical Committee, were chosen.

The various organisations within the National Medical Union retain their individuality but are federated together under a common board of management. To this central or national body each member must pay a guinea per annum, and he further subscribes to his local group whatever may be needed, though this does not often amount to more than 5*s*. a year. A preliminary official statement of the objects and policy of the union has been issued and already published; but for the sake of sequence it may be useful to repeat it here. The object of the National Medical Union is:—

1. To maintain the freedom of the medical profession in its professional and personal relations with the public.
2. To support the public in maintaining a corresponding freedom, and to safeguard the national health.
3. To oppose the present arrangements for medical benefits under the National Insurance Acts, and to decline professional service under such arrangements.
4. To preserve an independent attitude with regard to party politics.

Such, briefly and officially, is the policy of the National Medical Union, and it has been growing in strength ever since its foundation. At first it had about 1000 members in the metropolitan area, including both general practitioners and consultants. To-day the membership has increased considerably, defections having taken place both from the National Medical Guild and the British Medical Association. Permanent offices have been taken at the *Morning Post* buildings, 346, Strand.

It is felt that, being organised, the non-panel associations will be able to make themselves heard when the time for a change in the working of the Act is at hand.

Future Developments.

It may seem strange that there should have been so many associations formed in about 12 months. The experienced organiser or student of public movements will be little surprised. A mass of persons taken as a whole, like, for instance, the medical profession, cannot be simultaneously moved by one single set of rules and principles. No one really knows what programme will prove acceptable to a working majority till some practical test has been applied. Then there are always two sorts of approval: the tacit approval and the assent that will be backed by action followed even by self-sacrifice. The former is only of service when there is no difficulty or serious opposition. Therefore, when a movement commences many committees and many organisations are started, rules proposed, and programmes prepared. Then ensues a struggle for existence resulting in the survival, not perhaps of the best, but of that which fits best the imperfections of the people for whom it is intended. Many alterations take place before experience shows what is most practical.

We have seen that when in the midst of the London Medical Committee the idea germinated that the best road to effective action would be the formation of a real trade union the National Medical Guild came into existence. But quite early in the life of the guild it was found necessary to admit practitioners who were working upon panels under the Act, for otherwise the guild could not be considered to represent the entire profession, which for a trade union would be ridiculous; and then the secretary of the guild himself went on a panel, I am informed. The end and aim of a trade union is to defend the trade interests of its members, and its business is to support or combat any particular Act of Parliament according to the manner those trade interests are affected. In this case the interests are professional and not trade interests, but the methods of attack and defence would be identically the same. When, however, both supporting and opposed to the formation of panels were represented on the guild, the possibility of united action was lost. I cannot see in a trade union the chances of united strength that are necessary.

Victims of Resistance.

Many stories are told of the suffering, the poverty voluntarily endured, rather than submission to what it was imagined would degrade the profession. Thus I heard, in the south-west of London, of a Scotsman, born and bred in the best traditions of the profession, who looked upon his work as a sacred ministry; when asked if he was going on the panel he was amazed beyond measure, exclaiming, "Man, it would be impossible to go on the panel." He felt that the profession had been "kicked on to the panel." If it was a case of "go on or starve," with great dignity he declared his readiness to starve. Many medical men thought they were rightly or wrongly forced into a contract which they had had but very little to say in preparing. They felt they were being ignominiously forced on the panel, and to go on the panel was to give way to compulsion. At Paddington an old-established practitioner, 60 years of age, declared that he could not do panel work. It might suit younger men, he said, but he would not undertake it. "A squatter," as he was resentfully described to me, came with an assistant and took a house immediately opposite. In a short time the servants, the shop assistants, and other insured persons went to the new-comer, who was on the panel. The old-established practitioner found his income so reduced that he had to dismiss his servants, rely on his daughters for the domestic work, and take a much smaller house. In Wandsworth there was a case of a practitioner whose patients were nearly all insured persons. But he had signed the pledge not to serve on the panel, so he refused to profit by a rich harvest, and nearly all his patients were taken from him. His loss was so heavy that it was proposed to raise a local fund, but he refused any such assistance. He declared that he had acted on principle, and was prepared to pay the cost. This story ended in tragedy. He had an attack of influenza, which should have been treated by rest, but he did not dare neglect the few patients he had remaining. Therefore he worked through his illness till he reached a point of exhaustion that was so severe that he died. This is a true story. The case will be recognised by many of my readers, and proves beyond all fear of contradiction the genuine dislike of the Act displayed by some medical men and still felt by them.

(To be continued.)

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

The University of Liverpool.

THE council at their last meeting appointed Dr. Warrington Yorke to the Walter Myers chair of parasitology, the chair established by the Liverpool School of Tropical Medicine in memory of Dr. Walter Myers, a former member of the staff, who lost his life on one of the expeditions organised by the school. Dr. Yorke is a Liverpool student, and had a distinguished scholastic career. During the last eight years he has been engaged in research in tropical medicine, and has served on an expedition to Nyasaland studying blackwater fever. Since the year 1909 he has served as director of the Runcorn Research Laboratory. At the same meeting Dr. W. Permewan was appointed to the lectureship in laryngology in succession to Dr. J. Middlemas Hunt. For some years Dr. Permewan has been in charge of the Department of Laryngology at the Royal Southern Hospital.

Royal Southern Hospital.

At the annual meeting of the trustees and subscribers of the Royal Southern Hospital, which was recently held with the Lord Mayor, Mr. H. R. Rathbone, in the chair, the annual report recorded a good year's work, 2957 in-patients receiving treatment, as against 2740 in the previous year. As regards out-patients, the effect of the National Insurance Act had been to reduce somewhat the attendances of trivial cases, for these had been referred, after the first treatment, to panel doctors. Notwithstanding heavy reductions in the income from annual subscriptions, donations, and the Hospital Saturday and Sunday Fund contributions, which, taken collectively, showed a diminution of £592 18*s.*, it was recorded with satisfaction that the ordinary income was in excess of the previous year by £158 17*s.* Against this small increase of income, however, there was a rise in the ordinary expenditure of £564 10*s.* This ever-increasing working deficit is causing the committee much alarm, and if the work and efficiency of the hospital are to be maintained it will be necessary for the public, especially the working classes who receive its benefits, to realise that this can only be done by increased support. The debt due to the bankers, it appeared from the report, had been increased during the year by £2249 6*s.* 5*d.* and on Dec. 31st last the sum owing was £6967 1*s.* 1*d.* The Lord Mayor, in moving the adoption of the report and accounts, referred to the very serious position in which that charity and others of a similar character in this city were placed at the present time. In almost every instance expenditure had gone up very seriously, and in nearly every case the income had been diminished. It showed that the support of the general public was not at all commensurate with the increased liabilities and increased demands for assistance from these charitable institutions. He was struck on examining the lists of subscribers to these institutions to find that the same names appeared again and again. They were composed of a comparatively small number of people, and he did not think it would be reasonable to expect these generous subscribers to increase the amount of their contributions. How were others to be approached? He would be willing to assist the medical charities of Liverpool by making a collective appeal to those who did not at present figure in the lists; but he thought it would be advisable to follow the matter up with personal applications. For this purpose he thought it would be well to have a subcommittee of each trade, profession, or business in the city who would know the men to whom they could apply with reasonable hope of success. He could not think that those who had not given had done so from a deliberate hard-heartedness or selfishness. If they were definitely asked to assist those who were in distress and suffering from sickness and unable to provide the medical relief they required for themselves, they would be willing probably to give every year a sum which, if it were given by every member of the community, would put the hospitals in a very different position from that which they had at present to report each year. He was having prepared a report of those who at present subscribed, and when he had it ready he would be able to indicate where the gap lay. Mr. Thomas Woodsend, the president of the hospital, seconded the adoption of the report, and thanked the Lord Mayor for his suggestions.

Foot and Mouth Disease.

During the last ten days an outbreak of foot and mouth disease has occurred in the lairage at Birkenhead, bringing business to a standstill at the Birkenhead and Wallasey lairages. On Feb. 23rd animals were discovered suffering from the disease in a shippon in Liverpool. Only two animals were affected, but all the animals at the infected shippon —32 in number—were ordered to be at once destroyed.

Feb. 24th.

MANCHESTER.

Noisy Schools and Physique of School Children.

THE Manchester and Salford District Education Association at its recent meeting in Manchester discussed some important directions in which school life in Manchester might be improved. One speaker pointed out the noisiness of Manchester streets generally, and suggested that around all buildings of a public character, such as churches, libraries, hospitals, and schools, silent pavements should be laid. In one district in Moss Side it appears that between 9 and 10 A.M. 120 cars go rattling and clanging past one school, in addition to miscellaneous traffic. While casement windows lessen the noise, they obstruct light, hinder ventilation, and make the school unhealthy. Of the 123,000 scholars in Manchester Mr. J. M. MacLachlan said that fully one-half were in a defective bodily state through one cause or another. In 1912 there were 1300 cases of anæmia, 600 of rickets, 6500 of malnutrition—i.e., 1 in every 20 children, 2600 cases of defective sight or external diseases of the eye, 560 of ear disease, 693 of defective hearing, many thousand cases of skin disease keeping the children from school, and 4800 cases of enlarged tonsils, adenoids, or glands. There were 6000 children with six or more carious teeth. A resolution was passed urging the city council to replace setts paving by wooden blocks or some other approved form of silent pavement alongside school buildings, beginning at once in respect of 16 schools in the noisiest parts of the city.

Tuberculosis Scheme for the County of Cheshire.

The Cheshire county council have approved the Public Health Committee's scheme for a systematic treatment of tuberculosis throughout the county area. The council undertakes to give sanatorium benefit to all insured persons on condition that it receives annually from the County Insurance Committee 7½*d.* of every 9*d.* available to them for such benefit, and that the Treasury contributes one-half of the net sum required. The scheme will cost a capital expenditure of £20,360 and an annual expenditure of £11,000. The county council, so far as the accommodation will permit, agree to provide sanatorium benefit on certain conditions for persons who are not under the Act. The county will be divided into four dispensary districts for the treatment and supervision of cases. At Chester there will be a central dispensary and four subdispensaries. Crewe will have two subdispensaries and the other two centres at Hyde and Northwich will also have two subdispensaries each. A tuberculosis officer will be appointed for each district to work under the county tuberculosis officer and in coöperation with the various other agencies of the public health service.

Burnley Hospital Extension.

Two years ago it was determined to raise £30,000 for a much-needed extension of the Burnley Victoria Hospital. It is announced that £30,200 have been promised or paid over to the institution. The extension will commemorate the jubilee of the borough's incorporation and the Coronation of King George.

Medical Tickets in Salford.

At the end of January about 92,000 new medical cards were sent out, and about 14,000 of these have been returned through the dead letter office. These people were nearly all members of Approved Societies.

Radium Fund for Manchester.

The subscriptions to this fund have now reached nearly £4000. A general committee has been appointed to secure a supply of radium for medical use in "Manchester and neighbourhood," with subcommittees, including a technical and scientific subcommittee, to report to the general committee on the subject of radium. It was agreed that there should be but one fund and one public appeal in the matter.

The Effect of the Insurance Act on Hospital Attendance.

At the yearly meeting of the governors of Ancoats Hospital it was stated that during the year there had been a large reduction in the number of minor ailments and accidents treated at the hospital. It is assumed that these infirmities are now being treated by the Insurance Act doctors. The number of in-patients during the year showed a very considerable increase, and the average type was of a more serious character. As to accidents, 504 of these cases were of such a serious nature as to call for immediate admission to the wards. During 1913 2115 in-patients and 8873 out-patients were treated. The number of accident patients totalled 21,898. The annual expenditure was about £10,000.

Feb. 24th.

BRISTOL.

University of Bristol: Colston Society Dinner.

THIS annual function was marked by some very interesting speeches. Both the guests of the evening, Principal E. H. Griffiths, of University College, Cardiff, and Professor H. H. Turner, of Oxford, spoke in warmly commendatory terms of the spirit of research which has made itself felt in Bristol. The Lord Mayor of Bristol also spoke of the beneficent effects of the scholarships which gave a chance of university education to those who were capable of profiting by it, and who would have lost that chance had it not been for financial help. The treasurer, Mr. Arrowsmith-Brown, reported that the year's collection amounted to £492, a sum which would be handed over to the Colston research fund of the University.

Bristol Hospitals and Subscriptions from Working Men.

Some interest has been aroused in hospital circles in Bristol by the movement set on foot by some of the local labour leaders to gain representation for working men on the governing bodies of the hospitals. It is argued, and with considerable reasonableness, that since they subscribe largely to the funds of these institutions the working men should be directly represented on the management committees. The labour leaders stated, at meetings held during the past month or two, that requests to this effect had been ignored or refused by the hospital authorities, and they had determined to carry by storm the position refused to them by more peaceable means. Their plan is to "pool" the working men's contributions (so far as they could secure them) and to allot to nominees the sums equivalent to a governor's subscription. The first engagement in this campaign occurred last week at the annual meeting of the Royal Infirmary. The labour representatives attended in force; their first speaker, Alderman Sheppard, used the moderation in argument for which he is notable, and asked for a consideration of the plans whereby the hospitals of other cities, Newcastle-on-Tyne and Leicester, had secured the confidence and support of the working men. Unfortunately his colleagues were less reasonable, and made vague insinuations against the treatment of patients which they were unable to substantiate. In his reply the president, Sir George White, repudiated these insinuations and passed over the other arguments brought forward. There is no evidence to show that these extremists represent the Bristol working man's attitude towards hospitals; nevertheless, it is probable that a good deal of misunderstanding between the institutions and their patients might be cleared up if the class from which the latter are mainly drawn were represented on the governing bodies of the former.

Bristol Royal Infirmary.

The conflict with the Labour representatives did not monopolise the interest of the infirmary annual meeting. The in-patients in 1913 numbered 5394, as against 5049 in the previous year (totals which include transfers from the preceding year in each case); this addition is explained entirely by the increased accommodation provided by the recent renovations. Out-patients fell from 58,923 to 42,051, an effect of the National Insurance Act. The total ordinary expenditure was £20,228, and the income £12,783. To this deficit has to be added that of £4857 carried over from last year. Moreover, in order to pay for the new buildings, erected at a cost of £137,000, invested capital to the extent of £83,448 has been spent. The committee claim that this step is justified by its results, and that the increased efficiency of the buildings thus procured would have gratified the pious donors of the endowments just sold. In accordance with this belief every investment to which no specific trust is attached has been sold.

Bristol General Hospital.

After 40 years' service, the secretary, Mr. William Thwaites, is retiring from his post to enjoy a well-earned rest. During this long term of office he has made many friends at the hospital, and the familiar presence will be very greatly missed. He is to be succeeded by Mr. T. W. Gregg, who was till now secretary to the Belgrave Hospital for Children. He has had considerable experience of institutional work. The new pathological department has been at work for some weeks, and constitutes a very important addition, not only to the hospital but also to the pathological resources of the West of England. It consists of a large laboratory admirably lit by windows extending the whole length of the bench wall and capable of accommodating at least six workers with ease, and a small private laboratory for the pathologist, Mr. George Scott Williamson, who has developed this department of the hospital in a remarkable way. These extensions set free the old laboratory for the use of students and at the same time provide space for original work.

Feb. 24th.

SCOTLAND.

University of Edinburgh: Honour for Professor Ehrlich.

THE Senatus Academicus of the University of Edinburgh have awarded the Cameron Prize in Therapeutics, which is given for "highly important and valuable additions to practical therapeutics," to Professor Paul Ehrlich, director of the Royal Institution for Experimental Therapeutics, Frankfort, in recognition of his discovery of salvarsan, of his researches on numerous synthetic organic compounds of arsenic, and of his important work on immunity.

Foundation of an Anæsthetists Society for Scotland.

A dinner was held on Feb. 20th at the Balmoral Hotel, Edinburgh, attended by anæsthetists from Edinburgh, Glasgow, Aberdeen, and Dundee, Dr. D. C. A. McAllum, of Edinburgh, in the chair. Edinburgh was further represented by Drs. Gibbs, Torrance Thomson, Jones, and Ross; Glasgow by Drs. Paton Boyd, Lamb, Napier, and Fairlie; Aberdeen by Dr. Johnston; and Dundee by Dr. Mills. Apologies were read from Dr. R. Home Henderson, of Glasgow, and Drs. Ogston and Robertson, of Aberdeen. At a business meeting held after the dinner it was resolved to form a society to be known as the Scottish Society of Anæsthetists, the objects of which should be "to further the study of the science and practice of anæsthetics, and the proper teaching thereof." It was resolved to limit the membership of the society to those practising the specialty of anæsthetics, but that other members of the profession interested in the subject should be invited as guests to the meeting to take part in the reading and discussion of papers. Office-bearers were appointed as follows: President, Dr. D. C. A. McAllum; Vice-President, Dr. J. Paton Boyd; and Secretary-Treasurer, Dr. J. Stuart Ross. Drs. Torrance Thomson, Lamb, Mills, and Johnston represent Edinburgh, Glasgow, Dundee, and Aberdeen respectively on the executive. It is intended to hold two meetings yearly in April and October, taking each of the four cities in rotation.

Royal Navy Medical Service: Address to Edinburgh Medical Students.

Surgeon-General A. W. May, Director-General of the Medical Department, Royal Navy, lately delivered an address to medical students in the New University Buildings, Edinburgh. Principal Sir William Turner, who presided, said that they wished to give a word of welcome to a very distinguished professional brother. Perhaps there was a stronger feeling amongst Scottish medical graduates towards the land services rather than the sea service. But they must keep this in mind, that Scotland was now about to become one of the greatest resorts for the Navy, and therefore the Navy would come home to them much more closely than it had done, and this was an appropriate time for the Director-General of the Medical Department of the Navy to come amongst them and tell them something about the Navy as a service. Surgeon-General May said that he had come to try to persuade some, at any rate, of the young men to join the Navy Medical Service. They were short of men in the Royal Navy at the present time. Giving the reasons for that shortage, he said that one was the fact that the medical service was judged greatly by the conditions which existed 35 years ago, and that it was judged unfavourably because at that time the service was not efficient. If, he said, they had an efficient service they would have a popular service, and he was glad to say that at present there existed no finer body of working medical men, especially in the younger branches of the service. The organisation and equipment of the hospitals were as fine as any in the world. The men they wanted were first-rate men, hard workers, and if they got those men they would be able to reward them as their work and their merits deserved. On the motion of Professor Harvey Littlejohn, the

Dean, a cordial vote of thanks was awarded to Surgeon-General May.

Dispute with Reference to the National Insurance Act.

A dispute has arisen between the miners of the Morningside district of Wishaw and the local doctors with regard to the payment of medical fees. Up till now the charge has been 2½*d.* per week, the money being deducted from the men's wages, but on the instruction of the county union the miners have decided to pay a contribution of only 2*d.* per week, and in consequence the medical men have intimated refusal to give attendance. The doctors are of opinion that the union has broken faith with them, the understanding being that country doctors were entitled to ½*d.* more per man than the remuneration given to town doctors. The dispute is a test one, as it is recognised that the outcome will affect the whole of Lanarkshire.

The Purification of the Clyde.

A deputation from the corporation of Glasgow and representatives of the county councils of Lanark and Renfrew, and the town councils of Rutherglen and Clydebank were received by the Secretary for Scotland last week to make representations on the question of the pollution of the River Clyde by sewage from the burghs of Paisley and Renfrew. The deputation urged that the corporation of Glasgow had already spent £2,500,000 on purification works, not to mention the sums spent by the two councils. It was also recalled that the burghs of Coatbridge and Airdie were, at the instance of the county council of Lanark, compelled by law to construct purification works. Hitherto Paisley town council have even refused to appoint a committee for the purpose of meeting with the Glasgow authority.

Glasgow Royal Infirmary.

During last year the patients admitted to the Glasgow Royal Infirmary were 9661, as compared with 8787 in 1912. The rate of mortality was 9·6 per cent., as against 10·17 per cent. the previous year. The daily average residing in the institution was 656·8. The total general attendances at the outdoor department were 128,637, as against 183,661 in the previous year, the decrease being probably due to the operation of the National Insurance Act. The total ordinary revenue was £28,427 and the total ordinary expenditure £53,548, leaving a deficiency of £25,121.

Feb. 23rd.

IRELAND.

The Dublin Housing Report.

THE report on the housing conditions of the working classes of the city of Dublin has given rise not unnaturally to much discussion and newspaper comment. The corporation, as was inevitable, has come in for severe censure. In a letter to the daily papers of last Saturday Sir Charles Cameron, medical superintendent officer of health, attempts to reply to some of the charges levelled at his department and at the civic management generally. He begins by charging the chairman of the committee of inquiry with bias, and with a desire to ignore all evidence in favour of the sanitary administration of the city. He goes on to show that in the last 35 years there has been a considerable reduction in the death-rate of Dublin. This, of course, is not denied, but nevertheless the death-rate is still the highest in the kingdom or, indeed, in Western Europe. With regard to the specific charges made in the report in reference to non-enforcement of the by-laws and improper granting of rebate of taxes Sir Charles Cameron's defence appears to fail.

Payment for the Certification Panels.

Much discontent has been naturally caused by the unexplained delay in making payment to the medical men who went on the certification panels at the invitation of the Insurance Commissioners last spring. Under the terms of the agreement accounts were to be settled quarterly, but more than ten months have elapsed without any payment being made. A recent communication to the County Cork Insurance Committee from the Insurance Commissioners is not likely to allay the anxiety of those to whom payments are due. Medical men going on the certification panel were assured that all insured persons who failed to choose a doctor would be allotted without delay, and they accepted appointment on the understanding that the entire money accruing to each area would be divided *pro rata* among the medical men on the panel for that area. County Cork was one of the areas in which the panel was declared by the Commissioners to be "completed." Nevertheless they have now declared that there were in that county several districts in which no facilities for certification were available for insured persons, and they refuse to make any payment in respect of insured persons in such areas. The point is in essence the same as that which has arisen in the county of London with regard to unallotted insured persons. The Irish Commissioners appear, however, to be bound by the terms of the agreement to make full payment. Medical men in other panel counties will wait with interest to know whether the Commissioners intend to attempt similar deductions in these areas.

Forster Green Hospital, Belfast.

Dr. F. Coates has been appointed honorary attending physician to the Forster Green Hospital, in place of Dr. J. E. MacIlwaine (resigned), and Mr. W. McCready, laryngeal surgeon, in room of the late Dr. C. Shaw.

Infantile Paralysis in Fermanagh.

As a result of the outbreak of poliomyelitis at the Irvinestown district of County Fermanagh two deaths have occurred. The Local Government Board has sent down one of its medical inspectors to make inquiries, and unfortunately a good deal of panic has arisen among the inhabitants, and in numbers of cases children are being sent out of the district. As to how the disease is spread, we are completely ignorant.

Feb. 24th.

PARIS.

The Reform of Medical Education.

THE Conseil Supérieur de l'Instruction Publique at its last meeting dealt with two questions touching medical education. The first was the situation of *professeurs agrégés* of the Faculty. These are nominated at the *concours*—under conditions which periodically give rise to lively protests—for a period of nine years, during which they take a course and undergo examinations. For teaching they are grouped in sections as specialists. For a long time the *agrégés* have complained of the temporary character of their position, and have even demanded that their appointment should have the same duration as that of the professors, being prolonged to the ordinary age limit—viz., 70 years. The Conseil Supérieur has not acceded to this plan, but has agreed that at the termination of the appointment this extension should be accorded as a grace to the *agrégé* on a vote of the Council of the Faculty and the Consultative Committee of Public Instruction. These *agrégés* will receive the title of *professeur adjoint*, but the number of such professors in each faculty must not exceed one-sixth of the number of titular chairs. Moreover, if necessary, *agrégés* whose term came to an end before November, 1913, may be recalled to service for a term of one to three years. The second part of the decree deals with the organisation in the faculties of the complementary and post-graduate instruction. This instruction concerns especially (1) candidates for teaching posts or for public offices requiring medical knowledge; (2) students who desire to extend their studies after taking their degree, or to specialise; (3) students in their final term and medical men who desire to improve their acquaintance with the laws affecting medicine and the study of the difficulties that the practice of medicine raises; (4) medical men desirous of keeping themselves in touch with recent methods and discoveries; (5) foreigners who come to France to complete their instruction; (6) travellers who wish to pursue their personal researches in the laboratories or cliniques. Each faculty of medicine, after consultation with the council of the university and with the consent of the Minister, will create and organise its complementary and post-graduate courses according to the resources at its disposal and the particular needs of each of them.

The Return to Type.

A recent report by Dr. J. Laumonier to the Société Française d'Eugénique is of present interest, since nowadays nearly all the great nations receive a certain proportion of foreign immigrants, who by marrying natives give origin to half-breeds. Now, it is well known that half-breeds are not a stable type and that their descendants after a few generations revert to the type of one or other of their original progenitors. Dr. Laumonier claims to have shown that the greater persistence occurs in the type longest settled in the land. It would thus seem that a foreign population, introduced and fixed by marriage, loses its ethnic personality in succeeding generations, and that it is the indigenous type which finally persists.

The Serum Diagnosis of Tuberculosis.

M. Debains and M. Jupille would appear to have made a great advance in a recent communication to the Société de Biologie. They showed that Besredka's tuberculin, which is obtained by cultivating Koch's bacillus in egg bouillon, forms alexins in the presence of tuberculous serum from whatever form of clinical tuberculosis. This reaction is very sensitive, and is always specific, save in certain truly exceptional circumstances. It takes place with lesions that are developing. Its value is greater than that of the cutaneous reaction in that it gives an affirmative diagnosis, even when the clinical signs of tuberculosis are doubtful or altogether absent. It is absent only in those tuberculous patients who are severely afflicted and at the point of death, and in those who are already on the road to cure. It is superior to the ophthalmo-reaction in that its application entails no risk.

The Traffic in Habit-forming Drugs.

Severe sentences, varying from 200 to 2000 francs penalty (with 300 francs damages in one case) and one month in prison, have recently been passed in France upon five pharmacists for selling morphia and other habit-forming drugs. Of five wholesale druggists also inculpated two were mulcted in damages. The judge's charge, which was in very severe terms, pointed out that stringent measures are now demanded, since drug addiction is no longer confined to neurotics and rich degenerates whose extinction would be no loss to the community, but is extending also among workers and university students.

Feb. 23rd.

BERLIN.

The Berlin Invalidity Insurance Institution.

THE annual report of the Invalidity Insurance Institution — Landes - Versicherungs - Anstalt — for the city of Berlin states that since compulsory insurance has been extended so as to include orphans and widows the number of persons connected with the institution is about 1¼ millions. It must be remarked that the above institution is concerned only with the city of Berlin proper, having about 2½ millions of inhabitants, and not with the suburbs, which have an additional population of 2 millions belonging to the insurance institution of the province of Brandenburg. The income of the institution derived from the compulsory contributions of employers and working people was about 15 million marks in the year 1912; whilst the property of the institution was about 100 million marks. Of this sum about 36 million marks are invested in mortgages on asylums, sanatoriums, hospitals, homes for invalids, hygienic dwellings, &c.; about 20 million marks represent the value of the hospitals and sanatoriums belonging to the institution. The disbursements included sick pay to 49,621 men and 27,052 women, and old age pensions to 6548 men and 1611 women. Tuberculosis was the cause of invalidity in 19·1 per cent. of the men and in 14·4 per cent. of the women. The prophylaxis of tuberculosis is one of the most prominent works of the institution. In the sanatorium at Belitz 18,724 tuberculous patients were attended during the period 1908–12, at an expense of 10 million marks. Apart from the sanatorium for tuberculosis there is also in Belitz another one reserved for the treatment of other internal diseases, and in it 13,737 patients were treated, at an expense of 4·5 million marks. The united sanatoriums of Belitz are the largest in existence, the number of beds being about 1800. The institution also possesses in Lichtenberg, a suburb of Berlin, a receiving house in which doubtful cases are first examined until it can be decided if they are to be taken to Belitz. A day sanatorium is also combined with this house. Throughout the city there are numerous dispensaries, the nurses of which made 23,958 visits to tuberculous families, and the result of these visits was that in 225 cases more rooms were hired at the expense of the institution. In 915 cases the dwellings were disinfected. The institution has also an extensive dental department, where nearly 7000 patients were treated in 1913.

Proposed Neutrality of Watering-places and Health Resorts in Time of War.

Professor Kisch, of Marienbad, has published a proposal that watering-places and health resorts should be used for the accommodation of sick and wounded soldiers in the event of war. He said that in time of war these places were completely abandoned by civilian patients, and that owing to their hygienic arrangements and the great number of beds provided in them the residential buildings might be regarded as large and well-equipped hospitals. For that purpose, however, it would become necessary to modify the Geneva Convention so that the health resorts and watering-places should be declared neutral and placed under the Red Cross just as hospitals are. In this way the possibility of street fighting would be avoided. Professor Kisch suggests that the Red Cross societies might take the necessary steps for approaching their respective Governments in support of his proposal.

The Climate of the African Desert.

An expedition for the study of the climate of the desert and its influence on the human subject will be sent to Egypt on behalf of the Physiological Institute of the University of Berlin. The expedition will start in the beginning of March, proceeding first to Helouan and then to Assuan. Investigations will be made on the metabolism of water and of nitrogen, on the respiration, the blood, and the nervous system. The expenses will be covered partly by the Government and partly by a legacy left by the late Countess Bose to the University of Berlin for scientific research.

Socialist Medical Men in Berlin.

Medical men belonging to the Socialist party have lately formed a society under the presidency of Dr. Zadek, a member of the Berlin municipal council. It has been suggested in the press that the new society might possibly in the future take up a position of antagonism to the bulk of the profession when strikes were in progress, and might help the sick clubs (of which very many are under the control of the Social Democratic party) in their struggle against the profession. The members of the new society have, however, declared that they are far from thinking of doing this, but that they will advise the Socialist party in medical matters better than has hitherto been the case; they hope to be able by their work to contribute to the establishment of better relations between the clubs and the profession. The society has already about 100 members. This is the first instance in this country of an organisation of medical men according to political principles.

Feb. 23rd.

CANADA.

Handsome Donation to National Sanatarium Association.

Mr. W. J. Gage, of Toronto, has recently given a further contribution of $100,000 for the prevention of tuberculosis throughout Canada, bringing his total gifts to a quarter of a million dollars. The amount will be employed in providing for needy patients in the Muskoka institutions. Mr. Gage is practically the founder of the sanatorium movement in Canada, and it is through his efforts that sanatoriums have sprung up in almost every section of Canada. Since the National Sanatarium Association was founded it has taken care, practically free of cost to themselves, of over 7000 patients in its various institutions, and there are now in the Muskoka and Weston and Humber institutions about 470 patients. The plant and equipment of all these hospitals is valued at $500,000.

Toronto School Children.

A report regarding mental defectives in the publi schools of Toronto states that between 250 and 3 pupils are mentally defective. The Minister Education has not yet exercised the powers con ferred upon him in 1911 by the Act of the Ontari Legislature authorising the establishment of speci classes. There are also said to be 45,000 schoo children with decayed teeth, and between 20,00 and 25,000 with septic mouths. It is proposed t establish six additional dental chairs.

Typhoid Fever in Toronto.

Fifty deaths occurred from typhoid fever i Toronto in 1913, as against 150 in 1911. In 24 o the 50 the disease had been contracted outside th city. Altogether the typhoid death-rate was 11 pe 100,000 population; but as only 26 deaths can pro perly be attributed to conditions in the city, th rate would be 5·8. There are only four cities o over 350,000 in North America with a better recor —viz., Cleveland, 6·3; Cincinnati, 7·3; St. Louis 10·2; New York, 10·4.

Typhoid Fever in Ottawa.

For the past 15 years Ottawa has had a great dea of typhoid fever. From 1901 to 1910 there were about 200 deaths from this cause. Within 1 months in 1911 and 1912 two epidemics occurred with 165 deaths. The New York expert, Mr. Allan Hazen, has recommended, amongst other things, the hypochlorite treatment of the water-supply. In March, 1911, the Canadian Conservation Commission with the Ontario Board of Health and the cooperation of other sanitarians investigated the causes o typhoid fever in the capital, and agreed that the Ottawa water-supply was polluted chiefly from the south shore of the river. After the epidemic of 1912 Mr. Hazen prepared a complete scheme of a water plant for Ottawa, which was endorsed by the Ontario Board of Health and accepted by the corporation of Ottawa, subject to ratification by the citizens. But at the municipal elections in Ottawa on Jan. 1st, 1913, the ratepayers rejected Mr. Hazen's scheme. On Jan. 7th Mr. Justice Lennox quashed a by-law passed by the Ottawa city council providing for the expenditure of $13,000,000 on a new waterworks system. He declared it illegal and improper, the sole ground upon which it had been passed being a *fiat* by the chief officer of health for Ontario. He had acted doubtless in the public interest, but had exceeded the powers conferred on him by the Ontario Legislature. There was no doubt as to the absolute necessity for a pure water-supply for Ottawa; it was all a question of procedure. If the citizens refused the appeal of the city council the right procedure was through the Ontario Legislature. On Jan. 1st, 1914, the ratepayers again rejected the scheme. An epidemic in Ottawa cannot be altogether a local matter, but would be of national and international concern, Ottawa being Canada's seat of government, so that the situation is serious.

Meat Extracts in Canada.

Bulletin No. 267 of the Laboratory of the Canadian Inland Revenue Department reports on 80 samples of meat extracts purchased throughout Canada. The Canadian standard requires 50 per cent. of solids in fluid meat extracts. Of the 80 samples analysed 12 were solid meat extracts, 25 were normal meat extracts, and 42 were fluid meat extracts; one was a meat juice. In all the solid extracts the ash and salt exceeded the limit named by the Canadian standard. Fat was in decided excess in 17 samples. The Canadian *standard for nitrogen content*, 8 per cent. of the total solid matter, was met by all but four of the samples. Favourable notice was given to most of the samples, and their keeping qualities appear to be of the best.

Verdun Protestant Hospital for the Insane, Quebec.

During 1913 477 men and 433 women were treated in the Verdun Protestant Hospital for the Insane, near Montreal. There were 247 admissions. Of 151 discharged 74 had recovered, 45 improved, and 32 unimproved. There were 92 deaths. The percentage of recoveries was 31·62; of deaths, 10·10. The youngest patient admitted was 15 years and the *oldest* 88 years. There were only eight voluntary admissions. Receipts were $159,938, expenditure $162,465, deficit $2,527. The Quebec Government contributes $142 per patient per annum.

"Audi alteram partem."

AN INTERNATIONAL INSTITUTE OF PATHOLOGY.

To the Editor of THE LANCET.

SIR,—No one will be disposed to deny that humanity is becoming more homogeneous. Local boundaries and prejudices are passing away with the increase in the means of communication and rapidity of transit. "International" is the "leit-motif" of to-day. The opening of the Palace of Peace at The Hague last year is the outward expression of this sentiment and, though the project has been heaped with ridicule, still, taken merely as a feather in the wind, any thoughtful mind must regard it as of real import.

Art and science have always been regarded as international, and in medicine the names of Pasteur, Lister, Virchow, and Koch must ever be classed among the extra-national in that their work knew no national frontiers. What was so nobly said to Lister might [illegible] be said of them, "Not a [illegible] kind, with uncovered head, salutes you." The world now has a "Palace of Peace." Why should it not also have a "Palace of Pathology"?

In this country already the Insurance Commissioners have at their disposal a substantial annual grant for original research. Working on these lines, why should we not see an international institute of pathology established on some neutral territory and subsidised by contributions from the governments of the civilised world? All medical material, other than clinical, might be sent to this International Medical Commission; thither all medical publications, irrespective of country or language, duplicate slides of all unusual pathological sections and bacterial cultures, might be sent for adjudication. But who are to be the adjudicators? This problem might be left in the hands of the Permanent Commission of the International Congresses of Medicine. Is it a chimera to conceive a series of medical scholarships subsidised by the contributing nations and allotted on similar principles to the Rhodes scholarships? Statistics, too, might converge on this institution, and thus much of the overlapping which individual national effort shows to-day be avoided. The *project is a* vast one and would require infinite elaboration. I merely submit it, in all humility, for what it is worth. I am, Sir, yours faithfully,

W. B. AINGER, F.R.C.S. Eng.

Sloane-street, S.W., Feb. 23rd, 1914.

THE MEIOSTAGMIN REACTION IN THE DIAGNOSIS OF CANCER.

To the Editor of THE LANCET.

SIR,—The brilliant results which have been achieved on the Continent by Ascoli and a great number of other workers by means of the meiostagmin reaction must make this a question of importance to all who are interested in the early diagnosis of malignant disease.

The object of this communication is to give a *résumé* of 18 months' work on this subject, and to point out that the results obtained in England—or, at any rate, in Scotland—do not accord with the very favourable statistics reported by workers in Italy, Germany, and Belgium. It is difficult to believe that Scotch blood sera differ from continental sera, and so one is forced to inquire if the malignant disease found here does not differ in some respect from that found in those countries. The technique can hardly be at fault, as the writer was very *kindly instructed by Ascoli and Izar in* the laboratory in Catania; and the later experiments, reported below, were done in collaboration with Dr. Urizzio, who had previously obtained most successful results while working in Vienna, Heidelberg, and Trieste. In the experiments many antigens were tried—various extracts of malignant tumours, *pancreas extract, pancreas extract* + cholesterin, myristil-agar, myristil-peptone, lecithin in toluol, and finally a mixture of linolic and ricinolic acids. With none of these were results obtained which could claim any diagnostic reliability.

With the pancreas extract there was a larger percentage *of negative reactions in non-malignant* cases—88·5 per cent., as against 61·3 per cent. with the malignant sera. However, with 11·5 per cent. of positive reactions in non-malignant cases the reaction was obviously without practical importance. Furthermore, the drop difference ("ausschlag") was not greater with serum than with antigen (*pancreas extract) and* saline alone. The addition of a small quantity of cholesterin was found to neutralise, in part or altogether, the effect of the pancreas extract. With the linolic-ricinolic acid mixture as antigen, the results were still far from satisfactory. 87 malignant sera and 85 non-malignant were tested with this antigen. Of the 87 *malignant* sera 41 gave a positive reaction; of the 85 non-malignant sera 29 gave a positive reaction. In these figures were included a number of exudates—chiefly pleural effusions—11 malignant and 9 non-malignant. If these are excluded there remain 76 malignant and 76 non-malignant sera. Of the 76 malignant sera 29 gave a positive reaction; of the 76 non-malignant sera 23 gave a positive reaction. Only one serum gave a pronouncedly high positive reaction, a reaction which arrested attention. This was from a case of cancer of the mouth and tongue. The first examination of the serum gave a drop difference of 5·5. A second specimen of blood was taken several days later, and the drop difference on this occasion was 4·4. This case had been under treatment with X rays. The patient did not differ clinically from numerous others examined, where carcinoma of the tongue, throat, &c., was present and in which the serum yielded a negative reaction.

It is to be noted that almost all the pleural or peritoneal exudates examined gave a positive reaction—usually a very high "ausschlag"—even when there was no question of malignancy. Cerebro-spinal fluid from non-malignant cases may likewise yield a positive reaction, as may also hydrocele fluid.

After the above experiments were finished Dr. Urizzio came to collaborate with me at the Glasgow Royal Infirmary. 41 malignant sera and 44 non-malignant were examined. Of the 41 malignant sera, 25 gave a positive reaction—i.e., 60 per cent. of malignant cases were positive to the meiostagmin reaction. Of the 44 non-malignant cases, 36 gave a negative reaction—i.e., 81 per cent. of non-malignant cases were negative, and 19 per cent. positive. These figures, whilst undoubtedly better than those reported above, do not show that the meiostagmin reaction is of much importance to the clinician. The large proportion of definitely cancerous sera which give a negative reaction is sufficient of itself to exclude the test from the domain of practical diagnosis.

I am, Sir, yours faithfully,
ELIZABETH T. FRASER, M.D.Glasg.,
Late Assistant Bacteriologist, Glasgow Royal Infirmary,
Beit Memorial Research Fellow.
Feb. 18th, 1914.

METHODS OF INCREASING THE ACCURACY AND DELICACY OF THE WASSERMANN REACTION.

To the Editor of THE LANCET.

SIR,—After reading Dr. Thiele and Dr. Embleton's paper in THE LANCET of Feb. 21st, we feel that we are compelled to record our absolute dissent from their conclusions. We cannot help thinking that they have plunged somewhat lightly into this subject. They state that "the use of cholesterin and other anticomplementary substances ...... introduces a very serious source of error."

Cholesterin antigens have now been used for some considerable time as a routine in at least four important laboratories—namely, by Browning and Mackenzie in Glasgow, Hans Sachs in Frankfort, Swift in the Rockefeller Institute, and by ourselves at the London Hospital; and it would appear strange if the elementary points raised by Dr. Thiele and Dr. Embleton had not already received due attention. So far as we are concerned we dealt with these questions in our paper of 1912[1] which Dr. Thiele and Dr. Embleton have apparently overlooked. We showed at that time that the anticomplementary action of our antigen was slightly greater than that of the same extract without cholesterin, but it naturally occurred to us to use less of our antigen in order to make the anticomplementary effect equal to that of the old antigen. The great advantage which followed the use of our formula was therefore in no way dependent upon the anticomplementary action of cholesterin. All this work has been confirmed independently by Swift and others who have not published. In our opinion the experimental data given by Dr. Thiele and Dr. Embleton do not justify such sweeping deductions. The present place is not, however, convenient for pointing out in what manner they have obtained results absolutely opposed to ours.

Turning to the practical side of the question, we will only refer to one of the authors' concluding paragraphs. We find here a statement which we hope is only intended as a figure of speech and not as a statement of fact: "...... People who use anticomplementary antigens are continually reporting positive Wassermann reactions with anticomplementary sera from corpses, after anæsthetics and hypnotics, and in scarlet fever, &c." We do not know how many non-syphilitic conditions "&c." is intended to cover, or who has been continually making these reports. We have had a large experience of post-mortem sera, and our results have always been entirely satisfactory.

In the current number of *Brain* we have discussed many of these questions in detail. The conclusions are based, not only upon experimental work, but also upon the investigation of several thousands of patients.

We are, Sir, yours faithfully,
JAMES McINTOSH,
PAUL FILDES.
Bacteriological Laboratory, London Hospital, E., Feb. 24th, 1914.

[1] Zeitschrift fur Chemotherapie, 1912, i., 79.

THE PAYMENT OF FEMALE MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—We understand that the posts advertised in your issues of Feb. 14th and 21st for two medical inspectors under the Board of Control (Mental Deficiency Act) are identical as regards the work required, but the payment offered is different, being £350 rising to £550 for the woman, and £400 rising to £600 for the man.

The Association of Registered Medical Women, supported by the British Medical Association, has strenuously upheld the principle that where men and women are doing identical work the rate of payment should be the same. The attempt to obtain the services of a woman at a cheaper rate than those of a man is not only unfair to the woman, but is likely to introduce a form of competition between practitioners of the two sexes which will be prejudicial to both and to the best interests of the medical profession.

We hope that medical women will not accept the salary offered, and that the Board of Control will see fit to reconsider its decision and to remove the inequality. We are, Sir, yours faithfully,

JANE WALKER,
President of the Registered Medical Women's Association.
F. MAY DICKINSON BERRY,
Chairman of Committee.
Harley-street, W., Feb. 24th, 1914.

THE EDINBURGH MEDICAL GUILD.

To the Editor of THE LANCET.

SIR,—I shall be glad if you will kindly correct an error in the report of your Special Commissioner *re* Medical Practice under the Insurance Act in this week's issue of THE LANCET on p. 566, item 7. Edinburgh Medical Guild is described as "a local body." This is an error, as the guild is open to all medical men in Scotland who have not accepted service under the Insurance Act, and at present it has members from various parts of Scotland.

I am, Sir, yours faithfully,
FREDERICK PORTER, M.B. Edin.,
Honorary Secretary, The Medical Guild, Edinburgh.
Edinburgh, Feb. 21st, 1914.

⁂ The word "local" was used as opposed to the word "general."—ED. L.

DIABETES INSIPIDUS AND INFANTILISM.

To the Editor of THE LANCET.

SIR,—Your annotation on this subject in to-day's issue leads me to draw attention to some recent experiments which testify against the notion that diabetes insipidus and genital atrophy are ever really of pituitary origin. That the genital atrophy of the adiposo-genital syndrome of man does not depend on the posterior pituitary lobe was proved conclusively by the case of Maranon (1911): microscopical examination showed that a hæmorrhagic focus had destroyed the anterior pituitary lobe and had entirely spared the posterior. This case, then, seemed to show that the genital atrophy was brought about by the destruction of the anterior lobe.

But Marrassini and Luciani (1912), after a very extensive series of castration experiments in rabbits and many other mammals, found that macroscopic and microscopic changes in the pituitary were inconstant and insignificant when present. This was confirmed in 1912–13 by Degener and Livingston, who never found pituitary hypertrophy in castrated rabbits. In December, 1913, Iscovesco showed that a special lipoid extracted by him from the anterior pituitary lobe, when injected hypodermically into rabbits for a long period at regular intervals gave no genital changes in either sex on necropsy. In the same month Camus and Roussy, experimenting on dogs, concluded provisionally that polyuria and the genital atrophy of the adiposo-genital syndrome are probably not due at all to a lesion of the pituitary, even when, as often happens, a pituitary lesion is unquestionably present, but depend on a neighbouring parapituitary basal lesion which injures centres or paths which are intimately connected physiologically in a way at present unknown with the nutrition of the testes and ovaries. Cushing's unaccountable polyurias after hypophysectomy, then, were due to undiscovered parapituitary lesions caused by the operation; but pituitary operations do not always produce such lesions. In one of Camus and Roussy's dogs a total, or almost total, hypophysectomy was followed by an enormous adiposity with perfect integrity of its testes and sexual functions. Here the adiposity was due to the loss of the posterior pituitary lobe, and the genito-sexual integrity was due to escape of the parapituitary genito-trophic centre and path. It is, of course, true that the posterior pituitary lobe has a diuretic function, and so also (to a slight extent) has Iscovesco's special anterior pituitary lobe lipoid.

We are forced to conclude, therefore, in the present state of our knowledge, that while there are really such conditions as pituitary glycosuria and pituitary adiposity, it is highly probable, if not certain, that pituitary diabetes insipidus and pituitary genital atrophy have no existence in man, rabbit, and dog.—I am, Sir, yours faithfully,

London, N.W., Feb. 21st, 1914. LEONARD J. KIDD.

FRACTURE OF THE EXTERNAL MALLEOLUS.

To the Editor of THE LANCET.

SIR,—As the result of reading Sir John Bland-Sutton's interesting paper on the treatment of fractures of the external malleolus in THE LANCET of Feb. 7th, I am tempted to ask the following questions: 1. Whether as a routine he removes the external malleolus when fractured? 2. Is there any possibility of a valgus or varus condition of the foot resulting? Under such circumstances would a stiff ankle be better than talipes valgus or varus? 3. Is there any displacement of the peronei tendons, and if so, what means are taken to remedy such displacement?—I am, Sir, yours faithfully,

B. WHITCHURCH HOWELL.

Great Portland-street, W., Feb. 19th, 1914.

GLANDERS IN HUMAN SUBJECTS.

To the Editor of THE LANCET.

SIR,—May I trespass on your space and in view of the cases of glanders in human subjects recorded in THE LANCET of Dec. 13th, 1913, p. 1696, by Mr. H. M. M. Woodward and Mr. K. B. Clarke, direct your attention to the very interesting case of chronic glanders in a shoemaker described in the *Nederlandsch Tijdschrift voor Geneeskunde*, Nov. 22nd, 1913, by Messrs. J. W. van der Valk and H. J. M. Schoo, of Amsterdam?

This is the first case recorded in Dutch medical literature. Full bacteriological examinations were made and excellent plates are given.

I am, Sir, yours faithfully,

HUBERT M. BOSHOUWERS, M.D.

Antofagasta, Chile, Jan. 22nd, 1914.

THE RÔLE OF SYPHILIS IN MENTAL DEFICIENCY AND EPILEPSY.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 14th you mention the importance of the systematic examination of the mentally deficient both clinically and by the Wassermann reaction, and you refer to the recent pioneer work in England of Dr. K. Fraser and Dr. H. F. Watson.

I should like to point out that in the sixty-seventh report of the Commissioners in Lunacy published in June, 1913, and in our tenth annual report for the year ending March 31st, 1913, I published the results of my investigations into the incidence of syphilis among 163 mentally deficient patients then resident at this asylum.

I am, Sir, yours faithfully,

W. REES THOMAS,
Senior Assistant Medical Officer and Pathologist.

East Sussex County Asylum, Hellingly, Feb. 23rd, 1914.

LONDON: ORGANISATIONS FORMED TO COMBAT THE ACT.

To the Editor of THE LANCET.

SIR,—I am instructed to correct a slight inaccuracy in the account published with this sub-heading in your issue of Feb. 21st.

Definition 6 which reads: "6, National Medical Union, formed in Manchester, and now the federating body for non-panel associations" is not quite correct, inasmuch as the federation is a new body formed at London at a Conference of Non-Panel Associations held on Nov. 29th, 1913.

Definition 6 should therefore read: 6, National Medical Union, formed in Manchester, now a unit of the Federation of Non-Panel Associations under the title of "Manchester District."

This entails the addition of a thirteenth definition: 13, National Medical Union, a federation of non-panel associations formed at London on Nov. 29th, 1913, at a conference of delegates representing over 1000 non-panel practitioners in various parts of Scotland and England. At this conference the Manchester society agreed to hand over the title "National Medical Union" to the new federation, itself adopting the designation of the Manchester District of the new body. The federation now known as the National Medical Union is distinct in origin, executive, and policy from the older body of the same name, which together with the Edinburgh Guild and various London non-panel associations has coöperated in a new establishment. I am, Sir, yours faithfully,

ROBERT CARSWELL,
Hon. Secretary.

346, Strand, W.C., Feb. 23rd, 1914.

THE PUBLIC HEALTH (OPHTHALMIA NEONATORUM) REGULATIONS, 1914.

To the Editor of THE LANCET.

SIR,—These regulations, dated Feb. 5th, 1914, together with a circular letter of the 6th inst., have just been issued by the Local Government Board to local sanitary authorities, extending the compulsory notification of this disease to every sanitary district in England and Wales. They come into force on April 1st, 1914.

The fee of 2*s.* 6*d.* will be paid to medical practitioners for each case arising in their private practice, or 1*s.* for cases in public institutions, or for Poor-law cases. Midwives will receive 1*s.* for any case, wherever occurring. The actual fees received will be 1*d.* less than stated, as the notifications have to be sent to the medical officer of health by the penny post, if not delivered by hand at the town-hall. If a practitioner and a midwife both notify the same case, are both to receive fees?

The issue of these regulations, besides future regular work, at once provides every medical officer of health with the necessity of finding time to (1) compose and issue a circular to all medical practitioners, resident *or* practising in the district of his local sanitary authority; (2) the same to all certified midwives; (3) prepare and issue, guided by the schedule to the regulations, books of notification forms (with counterfoils) for the use of the said midwives; and later on (4) prepare and distribute quarterly fee-account forms to all the aforesaid practitioners and midwives. For this considerable addition to his duties the medical officer of health gets no more remuneration, not even 1*s.* per case. So the Antitoxin Order, 1910, still retains its distinction as the only Order of the Local Government Board which impressed on local authorities that increased duties should bring increased salary to the poor medical officer of health.

No provision is made in these regulations for the enforcement of any penalties on practitioners or midwives who do not obey them. If the medical officer of health issues books of forms (as instructed) to midwives who practise in his district but do not reside there, a midwife may receive as many as three or four from different medical officers, causing much confusion, and then might notify a case to the right medical officer of health on the wrong book, or *vice versâ*. It should have been sufficient—as under the Tuberculosis Regulations, 1912—for each medical officer of health to provide books for those midwives *residing* in his own area. The term "child" is not directly defined, but from article I. (i) of the definitions one presumes that by "child" is meant "an infant less that 21 days old."

No time-limit of 36 hours, as in the Notification of Births Act (1907), or of 48 hours, as in the Tuberculosis Regulations (1912), is given, but a practitioner must notify "on first becoming aware" and a midwife "forthwith." Article VI. contains a phrase that will cause as much trouble as the "exemption section" of the Notification of Births Act (1907)—viz., that a midwife must notify "unless the case has been already notified by a medical practitioner." A converse exemption is supplied in Article V. (1 b) for a medical practitioner. The section of the Notification of Births Act referred to has greatly impaired the usefulness of that Act.

As only "certified" midwives are referred to throughout these latest regulations of the Local Government Board, I presume that the old-fashioned midwife, who is only *registered* and not certified by the Central Midwives Board, need not comply with the regulations.

The medical officer of health is an expositor of preventive and not of curative medicine. Therefore, under these regulations he cannot do more than endeavour to see that an infant notified as suffering from "ophthalmia neonatorum" has prompt treatment at the hands of a private practitioner or in a public institution. If the parent or guardian does not provide this, the medical officer of health can either urge his Council to prosecute the offender under Section 12 of the Children Act, or (that failing) bring the case to the notice of the local representative of the Society for the Prevention of Cruelty to Children.

I am, Sir, yours faithfully,

ENERGY.

Feb. 11th, 1914.

A NATIONAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—There can be no doubt that the articles in THE LANCET, the *British Medical Journal*, and the *Morning Post*, to which I alluded in my letter of Feb. 14th, discussed the question of "free choice" solely from the point of view of the importance of patients being able to choose their own doctor. Dr. Shaw challenged me to show how such "free choice" could be extended to patients under a State service, but instead of answering my suggestions he now shifts the argument to the question of doctors being able to limit their panels by their right of "free choice" of patients. If "free choice" means this right on the part of the doctors and not the right of the patients, then certainly I am "using the words 'free choice of doctor' in some different sense from that generally understood by the profession," but not different from that in which it was used in the articles referred to above, nor from that in which my colleagues in the State Medical Service Association use it.

Dr. Shaw approves of the panel system because doctors are placed in competition to secure patients [illegible], and because success in doing so [illegible] *remuneration.* It is just this system of trying to please patients for the sake of personal gain that seems to me and other advocates of a State Service inadvisable. If this objection were removed by the formation of a whole-time salaried service, no one would be adverse to patients enjoying whatever therapeutic advantages there may be in "free choice of doctor" in so far as that were possible.

Dr. Major Greenwood asks: "Are all the 20,000 panel doctors to be paid uniform salaries, as is usual in a Government service ......?" I cannot think of any Government or municipal service where the whole staff is paid a uniform salary. The salaries vary according to seniority, rank, and the value of services rendered, and so it would be in a State Medical Service; there would be seniors, juniors, assistants and junior assistants, each grade receiving a different scale of remuneration. Amongst the panel doctors to-day there are partners, first, second, third, and even fourth in seniority, and there are senior and junior assistants, all receiving different rewards for their labours, though probably year in and year out they all do about the same amount of work. The present position and remuneration of each panel doctor could be made the basis of his rank and salary under a State Service to start with.

Surely to maintain that Poor-law patients have "free choice of doctor" because they can pack up and remove to the district in which the doctor of their choice resides would be ludicrous even if it were accurate. I believe that under the Acts of Settlement of Charles II. and 1835 the guardians would refuse them relief and bundle them back to the parish from which they came. Dr. Greenwood states: "Like all reformers of his kind Mr. Parker has not the slightest regard for vested interests. He does not consider in the least the present purchase value of medical practice ...." A statement of this sort is not argument and it is not true. It can only be made, like Dr. Shaw's reference to extreme Socialists and Shavian distrust, in order to prejudice the case for a State Service in the eyes of the profession. As it is impossible to go into every detail of such a big subject within the limits of a letter to the press, I will refer Dr. Greenwood to the concluding paragraphs of an article of mine published in the *Fortnightly Review* for May, 1913, where he will find that I not only recognise the necessity of guarding the vested interests of the profession during the transition stage from private practice to public service, but make various suggestions as to how this might be done.

In conclusion, may I say that neither Dr. Shaw nor Dr. Greenwood has answered the question I wished to raise—namely, whether the present methods of bringing the profession into touch with disease and of dealing with it were the best possible methods for securing a healthy nation. However, I have pleasure in noting that Dr. Shaw speaks of my "fair vision of extension of medical aid to every individual who needs it" with some approval, though he is content with present methods; whilst Dr. Greenwood apparently does not disapprove of the "highly coloured picture of the result to be obtained at the end of the journey," but doubts whether any Government having regard for its well-being could be found to put it into effect. Visions stimulate public opinion, and public opinion can put heart into Governments.

I am, Sir, yours faithfully,

Feb. 23rd, 1914. CHARLES A. PARKER.

To the Editor of THE LANCET.

SIR,—While opinions are divided on the advantages and disadvantages of converting the present panel system into a salaried State service, I think there can be only one opinion as to the advisability, indeed, the urgent need, for a modified State service in connexion with the panel system. I have ventured to suggest something of the kind at various times since the Bill was first published, and even among the bitter opponents of the Act what I now propose has been more or less cordially approved, in some cases, of course, *faute de mieux*, but for the most part with full acceptance of the importance of it both to the State and to the insured.

It is briefly this: that in each district there should be appointed consultants of proved ability who, upon adequate salaries, would give their whole time to the work of diagnosing cases sent to them by the panel doctors, and that, in addition to these consultants, there should be specialists in X ray work and in pathological analysis. Even the warmest advocates of the panel system cannot deny that it fails, and is bound to fail, in the treatment of organic diseases with obscure symptoms. Apart from the fact that few of the panel doctors have had the experience and the training which would enable them to diagnose the more subtle symptoms of organic disease, it is impossible for them to give the necessary time to such diagnoses. Within my own knowledge poor people suffering from ulcers and cancer of the stomach and intestines have been treated as cases of simple dyspepsia. One poor woman, who recently died from intestinal cancer, was from the first treated with bismuth and soda, and no one was so shocked as her panel doctor when he discovered too late what was the matter with his unfortunate patient. He was both skilful and kindly, but to diagnose such a case in the minute and a half—which is about the average he is able to give to each patient—would have been impossible for the best expert in Harley-street.

To the list of consultants should be added a specialist in malingering, to whom doubtful cases of that disease could be sent. If this plan were adopted it should be enacted that no patient should be put on benefit for more than a week, or at most a fortnight, without certification by the proper consultant. This provision alone would save the country many thousands in sick benefit, to say nothing of the economic gain of sending slackers back to work. To begin with, and perhaps permanently in some districts, it would be desirable to enlist the help (upon proper terms, of course) of the out-patients' departments of hospitals and of the better class dispensaries. Doubtful cases that do not get well within a fortnight under panel doctors' treatment should be sent to these institutions for diagnosis and certification or discharge.

I am, Sir, yours faithfully,

Feb. 23rd, 1914. X. Y. Z.

LITERARY INTELLIGENCE. — Messrs. Thomas Murby and Co. announce for early publication "The Mind at Work: A Handbook of Applied Psychology," edited by Geoffrey Rhodes, with contributions by Charles Buttar, M.D., E. J. Foley, and Professor L. L. Bernard, Ph.D.

THE AFTER-CARE ASSOCIATION.—The annual meeting of this association was held on Feb. 23rd in the library of the Royal College of Physicians of London, when Sir Thomas Barlow presided. The report showed that the experiment tried since the beginning of November last, in connexion with certain asylums in the south of England, of receiving mental patients discharged "on trial" had been satisfactory. The income from subscriptions and donations showed a slight decrease. Sir Thomas Barlow said that it was now recognised that those who had been afflicted ought to be set upon their feet again. Social problems could not be solved by leaving everything to be done by the State. Of the institutions which helped to bridge over for the poor the interval between recovery from illness and the return to wage earning, none deserved support more than the After-Care Association. The public mind should be disabused of the pessimistic idea that cases of mental disease were hopeless.

THE NATIONAL INSURANCE ACT.

THE GENERAL MEDICAL COUNCIL AND "OWN ARRANGEMENTS": A MEMORANDUM BY SIR DONALD MACALISTER.

A MEMORANDUM was presented by Sir Donald MacAlister, President of the General Medical Council, to the National Insurance Act Committee and the Executive Committee of the Council, on Monday last, Feb. 23rd, when these committees had under their consideration all the circumstances under which insured persons are entitled to make their own arrangements for the receipt of medical benefit. The memorandum runs as follows:—

The President desires to remind the committees that in November, 1913, he received and transmitted to members certain communications in which it was alleged that one or more Local Insurance Committees had entered into or sanctioned forms of agreement with unqualified persons, by which the latter undertook to provide medical attendance and medicines to insured persons who were permitted to "make their own arrangements" for medical treatment under the National Insurance Act. Owing to his illness the President was unable to be present at the meetings of the National Insurance Act Committee at which these communications were considered. The minutes of the meetings, at which Dr. Langley Browne acted as chairman, were laid before the Council at its November session and approved. The minutes showed that the committee were of opinion that the action taken by one at least of the Local Insurance Committees raised questions of grave importance as to the relation of the Medical Acts to certain Regulations made under the Insurance Acts. As it appeared doubtful whether the Local Committee in question was acting with the official sanction of the Insurance Commissioners, inquiries were addressed to the latter, and, as will be seen from the annexed correspondence, objections of a legal character were urged in the public interest against the Local Committee's proceedings.

The Chairman of the National Health Insurance Commission for England (Sir Robert L. Morant) met the Council's committee on Nov. 27th, 1913, and after a statement made by Dr. Norman Walker, at the request of the committee, in regard to the changes in their Regulations which it was desired that the Commissioners should make in respect of unqualified persons, a discussion took place on the questions thus raised. Sir Robert Morant agreed that the objections that had been raised to some aspects of the action of the Local Committee were valid, and stated that its procedure had apparently been adopted under a misapprehension. At the same time it was the case that, as had been explained by the Government during the consideration of the Bill in Committee in the House of Commons, under the provisions of the present Section 15 (3) it was open to Insurance Committees, if they thought fit, to allow insured persons who so desire to make their own arrangements, subject to certain conditions, with persons not medically qualified, and to receive a contribution towards the cost thus incurred. The 1913 Regulations contained no reference to this matter, and therefore made no special provision for such cases. It was thus impossible for the Commissioners to prevent the recurrence in those cases of action such as that referred to without issuing new and explicit Regulations dealing with the case of arrangements with unqualified persons.

Sir Robert Morant stated that the Commissioners, in drawing up the amended Regulations and Memoranda for 1914 (which were already in course of preparation) would be prepared to meet the wishes of the Council in regard to the objections in question. By making the requisite amendments in the Regulations and issuing instructions to Local Committees they would set forth clearly that the procedure to be adopted in the case of "own arrangements" made by insured persons with qualified practitioners was not applicable to the case of "arrangements" which certain insured persons might be permitted by the Insurance Committee to make, on their own responsibility, with unqualified persons. It was beyond question that, in the case of arrangements made by insured persons with unqualified persons, some of the conditions of the Exchequer Grant—for instance, the undertaking to give domiciliary treatment for tuberculosis in accordance with the Local Government Board Order—could not be fulfilled. As to a point which had been raised about medical certificates furnished to Approved Societies by insured persons when claiming sickness benefit, Sir Robert Morant stated that no question arose as to treating any statement of an unqualified person as a medical certificate. The rules of Approved Societies require the society to be satisfied by a medical certificate or other *evidence of incapacity before admitting the claim* to sickness benefit. Any such statement will be merely evidence which the society may have to consider in adjudicating upon a claim for sickness benefit in accordance with its rules. Responsibility for weighing that evidence rests with the society.

After further discussion, Sir Robert Morant repeated that the Commissioners, in the revision of the Regulations then in progress, would gladly give the fullest possible effect to the wishes then expressed to him on behalf of the Council, and in particular would endeavour to secure that the memoranda and official forms now to be issued by the Commissioners on this subject, for the guidance of local committees and others concerned, should be worded with a view to avoid misunderstanding. Every effort would be made to exclude phrases which might seem to afford occasion for any contravention of existing statutes bearing on the subject. Nor would the Commissioners approve any procedure which failed to make the necessary discrimination between the unqualified person and the practitioner who is "duly qualified" according to law.

The letter written by the President at the request of the Council in order to give formal expression to its views, and the letters sent by the Commissioners in reply thereto, are appended. The new Regulations issued by the Commissioners in pursuance of the above-mentioned discussion have been circulated to members of the Council, and published for general information. The new Memorandum (191/I.C.) of the Commissioners, explaining more fully the purport of Regulation 44, is circulated herewith.[1]

These documents appear to the President to give substantial effect to the wishes which the Council requesteed him to express to the Commissioners. He is satisfied that the Commissioners fully apprehend that the Council attaches great importance to its contention that nothing should be done, by administrative action, which would tend to defeat the purpose of the Legislature in framing the Medical Acts—namely, "to enable persons requiring medical assistance to distinguish qualified from unqualified practitioners"; or which might be deemed to confer official "recognition" on persons who according to law are "unqualified" and are prohibited from assuming the status and responsibilities of registered medical practitioners. He submits the Regulations and Memorandum to the Executive Committee in the belief that his colleagues will desire to acknowledge cordially the readiness the Commissioners have shown to consider the representations made to them, and to remove difficulties which have arisen in connexion with the local administration of the National Insurance Act.

Feb. 23rd, 1914. DONALD MACALISTER, President.

The following are the appended letters:—

A

General Council of Medical Education and
Registration of the United Kingdom,
299, Oxford-street, London, W.

No. 34946. *9th December*, 1913.

DEAR SIR ROBERT,—The General Medical Council has learned that one of the Local Insurance Committees has recently approved a form of agreement, between certain insured persons and a person who is not qualified under the Medical Acts, by the terms of which the latter undertakes to provide the insured persons with medical attendance and medicines, to give the domiciliary treatment included as a part of Sanatorium Benefit, and to furnish such certificates as may be required to enable the insured persons to obtain the several benefits of the National Insurance Act.

The Council has no reason to believe that the form of agreement in question has received the official approval of the Commissioners; and I am now, on behalf of the Council, writing to ask that the Commissioners should formally intimate their disapproval of it to the Local Insurance Committee.

---

[1] The Memorandum of the Commissioners was published in THE LANCET of Feb. 14th, p. 502.

The information in the possession of the Council makes it clear that the form of agreement employed in this case is appropriate only to an arrangement made with a legally qualified practitioner, and that some of the undertakings it contains cannot be legally carried out by an unqualified person. I am advised that such agreements are in fact invalid, inasmuch as they contravene the provisions and defeat the purpose of the Acts regulating medical practice in this country. If such action on the part of the Local Insurance Committees were to become general, it would moreover, in my opinion, defeat the objects of the National Insurance Act itself.

The Council is confident that the Commissioners will realise the importance in the public interest of the question of principle thus raised; and that they will take all proper steps both to bring to an end the procedure to which objection is taken and to inform the authorities who may be concerned that, in connexion with the administration of medical benefit, no valid agreement of the kind can subsist with an unqualified person.

I am, yours very faithfully,
(Signed) Donald MacAlister, President.

Sir Robert Morant, K.C.B.,
National Health Insurance Commission.

A note of formal acknowledgment was followed by—

C

National Health Insurance Commission (England),
Buckingham Gate, London, S.W.,
January 9th, 1914.

Dear Sir Donald MacAlister,—I write to say that we now have our new Medical Regulations practically completed containing paragraphs that will make it possible to deal, in the way that the General Medical Council indicated to be in their view desirable, with the various points about unqualified practitioners that were discussed at my meeting with your committee on 27th November; and I shall hope in a few days to be able to send you, as we arranged, a draft of the explanatory Circular and Forms needed in this connexion. I will send you copies of the new Regulations directly any are available from the printer.

When you receive them you will see that the subsections of the new Section 44 (formerly Section 49) set out in separate paragraphs the procedure to be followed in the case of those insured persons on the one hand who make "own arrangements" with unqualified persons, and those on the other hand who make "own arrangements" with registered practitioners. The words "in such manner" in the new Section 24 (formerly Section 14) mean that a special form will be required for use in these cases. The separation of Subsection (2) from Subsection (1) of the new paragraph 44 in the new Regulations makes it clear that the committee does not h[illegible] comparison between the treat[illegible]alified person and the treat[illegible]fied practitioner. Furthermore, under the new wording of paragraph 44 (4) it will be necessary for the Insurance Committee to make plain in any "own arrangements" with unqualified persons that there are some things required as conditions of the Treasury grant, which the unqualified person will not be expected to do (for the reason, of course, that he is not qualified for doing them), without for that reason precluding all possibility of contributions being made by the Insurance Committee towards the insured person's expenditure in such cases.

With the new Regulations thus clear on these points I do not think we shall now find any particular difficulty in arriving at suitable means for giving effect to what your committee indicated, when we draft the explanatory Circular and Forms; but I shall be glad if you let me know of any points in the latter, when I send them to you, which seem to you either not clear or inconsistent with what is in view.

I am, yours very truly,
Robert L. Morant.

On Jan. 19th Sir Robert Morant wrote, enclosing a copy of the New Regulations for Medical Benefit, and indicating that in Section 44 steps had been taken to make definite distinction between qualified practitioners and unqualified persons in the case of insured persons desiring to make their own arrangements; and on Feb. 14th the communication which follows was accompanied by the memorandum to Insurance Committees explaining generally the provisions of the Medical Benefit Regulations for 1914, governing "own arrangements" under Section 15 (3) of the 1911 Act, both with registered practitioners and with unqualified persons. This memorandum was published in The Lancet on that date through the courtesy of the Commissioners.

As regards the memorandum Sir Robert Morant writes to Sir Donald MacAlister:—

You will find, I think, that the two points which your Council pressed us to make explicit have been fully met, i.e.:—

(*a*) Attention has been unmistakably drawn to the distinction between "own arrangements" with registered practitioners and "own arrangements" with unqualified persons; and

(*b*) It has been made quite clear that Insurance Committees, in dealing with applications for "own arrangements" of the latter kind, are under no obligation to institute any comparison with the treatment afforded by a qualified doctor, or, indeed, to inquire into the nature or form of the proposals under consideration between the unqualified person and the insured person making his own arrangements.

Forms designed for the assistance of Insurance Committees in dealing with various types of applications for "own arrangements" have been prepared.

London Panel Committee.

The Insurance Commissioners have declared the following to constitute the first Panel Committee for the County of London to hold office until July 15th, 1914:—

Battersea—Knox, A. W., Richards, J. T.
Bermondsey — Jaynes, V. A., Richmond, B. A. (Chairman).
Bethnal Green—Grace, J., Sasun, D. D.
Camberwell—Batten, G. B. (Vice Chairman), Brenchley, A. D., Clatworthy, J. H., Esler, R., South, F. M. W.
Chelsea—Hudson, E., Orr, J. J.
City of London—Scanlan, J. J., Strong, R. H.
Deptford—Gooding, C. G., Payne, W. H.
Finsbury—Hockridge, T. G., MacGregor, R. D.
Fulham — Coltart, G. H., MacBurney, J. H.
Greenwich—Corfe, R., Hogarth, O. W.
Hackney—Keenan, T. F., Swan, A. T.
Hammersmith — Butler, J. A., Davidson, W. A.
Hampstead—Cunnington, C. W., Taylor, E. Claude.
Holborn—Two vacancies.
Islington—Jackson, J E., Patch, H. H. L., Sherry, J J. A.
Kensington — Atteridge, J. J., Carter, R.
Lambeth — Cazenove, W. R., Farman, R. J., Fraser, D. H., Taylor, H.
Lewisham—Donnellan, R. V., Hatfield, W. H.
Paddington — Angus, J. A., Williams, J. O.
Poplar—Cardale, H. J., Paxton, J.
St. Marylebone — Simpson, J. Pollock, Williams, R. Thorold.
St. Pancras—Fletcher, J. Corbet, Freyberger, L., Marshall, T.
Shoreditch—Two vacancies.
Southwark—Denning, J. V. C., Smith, F. J. Porter.
Stepney — Bernstein, M. M., Williams, W. O
Stoke Newington—Page, A. M., Welply, A. (Secretary).
Wandsworth — Biggs, A. C. B., McMurtry, W., Roe, A. D., Thomas, C.
Westminster — Roach, W. F., Starkie, R. F.
Woolwich—Clarke, J., Mair, A.
Women—Baker, Elizabeth, Bentham, Ethel.
Coopted—Mills, H. H., Shaw, Lauriston E. (Treasurer).

Medical Incomes under the National Insurance Act.

In view of the system of payment adopted in lieu of the capitation system at Manchester, and of the resolution of the Insurance Committee in that city to limit incomes to be derived from panel practice to £800 a year, the sums realised during the first year of the working of the Act by the 300 medical men who have gone on the panel in Manchester are of interest. The largest individual income has been £1980; 14 practitioners have earned between

£1000 and £2000; 11 between £800 and £1000; 32 between £500 and £800; and 47 between £300 and £500. Among those making incomes less than £300 per annum from panel practice, and particularly among 88 practitioners who have made less than £50, there are, no doubt, many who only attend as patients under the Insurance Act the servants and other dependents of their private patients in the wealthier neighbourhoods in which the bulk of their work is done. It will be interesting to set the above figures beside those that will record the working of the Act at Manchester during the current year. The figures given for panel practice at Leeds during 1913 form a useful comparison. Out of about 190 medical men on the panels there, 5 have made incomes of between £1000 and £1500, 7 between £800 and £1000, 25 between £500 and £800, and 27 between £300 and £500; 30 made less than £50. The above figures, of course, take no account of partnerships.

LANCASHIRE INSURANCE COMMITTEE.

At a recent meeting of the Lancashire Insurance Committee a request was made by the Medical Benefit Subcommittee for Chadderton, Crompton, and Royton that medical men on the panel should be supplied with drugs and articles likely to be required upon an emergency, and should draw from such a stock in the event of insured persons applying to them for treatment at a time when druggists' shops were closed. The practice of making up prescriptions from their own stocks of drugs and keeping an account in accordance with the requirements of the Insurance Committee in order to obtain repayment was found to take up a great deal of time. On the other hand, the clerk to the Insurance Committee pointed out that considerable clerical work would be entailed upon the committee if the proposed change were adopted. Eventually the subcommittee's recommendation was approved subject to the County Medical Committee and the County Pharmaceutical Committee being able to arrive at a working arrangement.

Medical News.

UNIVERSITY OF OXFORD.—The Philip Walker studentship in pathology, of the annual value of £200 and tenable for three years, has been awarded to Charles Joseph Singer, D.M., Magdalen College.—The following medical degree has been conferred:—

D.M.—F. O. Stohr, Trinity College.

UNIVERSITY OF BRISTOL.—In the final examination for the degrees of M.B., Ch.B., held recently, the following candidate was successful:—

Maurice Charles Barber.

Lieutenant-Colonel Sir David Prain, director of Kew Gardens, was nominated by the President of the Board of Agriculture and Fisheries as one of the three representatives of that department at the International Conference on Phytopathology held at Rome this week.

THE CAMPAIGN AGAINST INFANT MORTALITY.—On Feb. 24th the Queen attended a matinée at the Palace Theatre in aid of the Schools for Mothers in Fulham, Poplar, Shoreditch, and Stepney. These institutions are designed to give simple advice and instruction to working women, and are aimed directly against infant mortality. Originating in Ghent, these schools, which have now spread over Europe, were first tried in England at St. Pancras in 1907. They have proved a great success in many districts of London and in provincial towns, giving meals to women at a nominal cost for six months before and a year after the birth of a child, while medical men attend the schools twice a week, when babies are weighed and the mothers advised as to their own health and that of the children. Instruction in the making and mending of clothes is also given, the whole organisation being put at the disposal of the women for 1*d.* a month.

ST. GEORGE'S HOSPITAL.—The annual dinner of the Hunterian Society of this hospital will be held on Friday, March 13th, at the Waldorf Hotel, and will be followed by a smoking concert. Tickets for the dinner will be 6*s.*, exclusive of wine, and those desirous of being present should communicate with the honorary secretaries of the society at the hospital.

THE TRAINED NURSES' ANNUITY FUND.—The Countess of Hardwicke, Lady Barlow, Lady Champneys, Mrs. Charles Balfour, and Miss Sidney Browne, members of the council of the Trained Nurses'. Annuity Fund, have issued an appeal to nurses asking them to subscribe 1*d.* per month with the object of forming a benevolent fund. The address of the Trained Nurses' Annuity Fund, of which Princess Christian of Schleswig-Holstein is the President, is 73, Cheapside, London, E.C.

ASSOCIATION OF ASSISTANT MEDICAL OFFICERS OF ASYLUMS, ENGLAND AND WALES.—The executive of this association has issued a statement which is being sent to all members and clerks of visiting committees of public asylums in England and Wales. The statement summarises the various directions in which the association desires improvement in the terms and conditions of service of assistant asylum medical officers. These have been dealt with on several recent occasions in THE LANCET, and the case for reform was set out and discussed in a leading article on Jan. 10th last.

CONFERENCE ON THE TEACHING OF ANTHROPOLOGY.—Members of the Royal Anthropological Institute, representatives of the universities, and others interested in anthropology, met at the Drapers' Hall, London, on Feb. 19th, to discuss the practical application of the teaching of anthropology in the universities. Lord Selborne presided, and Sir Henry Craik, M.P., moved a resolution which approved the findings of the joint committee of the British Association and of the Institute, and declared that in the highest interests of the Empire the extension and organisation of the teaching of anthropology in the universities of Great Britain was necessary. Professor A. Keith, the president of the Institute, pointed out the lost opportunities for good which were the result of travellers to remote parts of the Empire not having sufficient knowledge of anthropology. The Institute wished to systematise all the information that it had gained and to place that information at the disposal of every university graduate. The resolution having been adopted, Sir Hercules Read moved that the chairman and members of the joint committee represent to the Prime Minister the views of the conference and ask for the appointment of an interdepartmental committee for advising as to the form in which the sympathy and support of the Government could be best expressed. Professor T. H. Warren seconded, and the motion, which was supported by Dr. W. L. H. Duckworth, Professor J. G. Frazer, and Dr. W. P. Herringham, was passed unanimously.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Elementary Education (Defective and Epileptic Children) Bill.

THE Elementary Education (Defective and Epileptic Children) Bill, which has been introduced into the House of Commons by Mr. PEASE, the President of the Board of Education, has been printed. It lays down that it shall be the duty of the local education authority for the purposes of the Elementary Education (Defective and Epileptic Children) Act, 1899, to make suitable provision for the education of children belonging to their area whose age exceeds seven years, and who are ascertained to be mentally defective within the meaning of the Act.

Inebriates Bill.

A Bill "to consolidate and amend the law relating to inebriates" has been introduced into the House of Commons by Mr. ELLIS GRIFFITH, the Under Secretary for the Home Department. It has been read a first time.

Higher Animals Protection Bill.

Mr. CATHCART WASON, with the support of Mr. COWAN and Mr. WEBB, has presented a Bill in the House of Commons "to prohibit the vivisection of the higher animals." It has been read a first time.

The Insurance Act.

In the House of Commons on Wednesday, Feb. 25th, an animated debate took place on a motion brought forward by Mr. HAMILTON to the effect that an inquiry ought to be instituted to report whether it was desirable to substitute a voluntary system for the compulsory system of insurance under the National Insurance Act. The discussion turned largely upon the financial stability of the existing system. The Chancellor of the Exchequer resisted the motion, admitting that in time it would be desirable to inquire fully into the working of the present Act. Mr. LLOYD GEORGE strongly combated the idea of a voluntary system. Mr. BONAR LAW, the leader of the Opposition, supported the motion, which was ultimately rejected by 283 votes to 199.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 18TH.

Hospital Accommodation in Jamaica.

SIR JOHN JARDINE asked the Secretary of State for the Colonies whether anything had lately been done by the [illegible] containing an extraordinary number of cases of syphilis —Mr. L. HARCOURT answered: In reply to the first part of the question, hospital accommodation in Jamaica has been steadily augmented for a number of years past both by extension of building and by provision of additional beds. Comparison of the Blue book for 1912 13 with that of three years before shows an addition of nearly 250 beds to the provincial hospitals. A new cottage hospital was provided last year at Ulster Spring, a district remote from existing hospitals. During 1911-12 and the [illegible] departments have [illegible] the latter [illegible] in the [illegible] t patients' [illegible] er 45,000. [illegible] by nearly 90 per cent., and in the current financial year nearly £11,000 has been provided for new works, as against £522 at the beginning of the period The answer to the last part of the question is in the negative, but special provision has been made to utilise the Government medical service for dealing with disease in such districts

Medical Treatment of Insured Persons.

Mr. R. GWYNNE asked the Chancellor of the Exchequer whether his attention had been called to cases in which insured persons, on moving their residence, had been refused medi[illegible] on the grounds that they ha[illegible] therefore in [illegible] in so acting, [illegible] the administ[illegible] Insurance Act; and, if so, what steps insured persons were to take to obtain ad[illegible] on the panel act[illegible] replied) said: No c[illegible] the notice of my right honourable friend Medical men on the panel have, of course, a right under the National Insurance Act, 1911, to refuse in the first instance to accept an individual insured person, but arrangements have been made whereby a medical man may be obtained by any insured person so refused If the honourable gentleman knows of a case where the arrangement has been broken I shall be very glad to know about it.

The Cost of Medical Treatment.

Mr. F. HALL (Dulwich) in the course of a question addr[illegible] the Trea[illegible] sons had [illegible] the case [illegible] oper medical treatment to insured patients; and whether it had been suggested to the London County Council that half of the deficiency should be met out of the rates —Mr. WEDGWOOD BENN (who replied) said: Under the arrangements entered into between Insurance Committees—including the London Insurance Committee—and the [illegible] can occur upon [illegible]

Sanatoria in Derbyshire.

Mr. [illegible] the Treasury whether [illegible] aken any steps to safe [illegible] iding to sanatoria in [illegible] of the provisions of [illegible] ational Insurance Act [illegible] prohibit the payment of [illegible] mittees to any sanatoria [illegible] which might refuse to respect conscience in the manner provided in the above mentioned subsection.—Mr. WEDGWOOD BENN answered: The duty of making arrangements to provide treatment for tuberculous insured persons in institutions or otherwise and of [illegible] treatment.

Sickness in Cradley.

Mr. G. LOCKER LAMPSON asked the Secretary to the Treasury whether his attention had been called to a report of a Worcestershire Insurance Subcommittee on the sickness in Cradley, in which statements of Mr Appleton, secretary to the General Federation of Trade Unions Approved Society, were admitted to the effect that the sickness rate amongst female workers in the district was enormous and was between 6 per cent and 7 per cent, or three times the normal; and whether, if this rate was continued until the first valuation, it would entail a very heavy levy on, or a reduction of benefits to, the compulsorily insured members —Mr [illegible] right honourable friend [illegible] appear that the figures [illegible] Approved Societies or [illegible] geographical districts a[illegible] the benefits of insured [illegible] will be governed after [illegible] pro[illegible] by t[illegible] or [illegible] members

Sanatorium Benefit in Fife.

[illegible] 49 persons have received treatment since that date.

A Case of Anthrax Poisoning.

Mr C. BATHURST asked the Home Secretary whether his attention had been directed to a recent inquest upon a waterside labourer who died in Guy's Hospital on Dec 21st [illegible] hich the jury, in returning [illegible] such poisoning, expressed [illegible] should extend the regula[illegible] which applied [illegible] wharves and [illegible] pigs' bristles were dealt with; whether he was aware that the Departmental Committee on Foot-and-Mouth Disease recently called attention to the danger of such substances, unless effectively disinfected, becoming carriers of anthrax and other animal diseases, and whether he proposed as the result of the above fatality to take any action in the direction suggested by the coroner's jury.—Mr. MCKENNA said in reply: The answer to the honourable Member's first two questions is in the affirmative The rules referred to cannot be extended in their present form to wharves or to any place other than factories and workshops [illegible] made under the old Factory Act of 1891, [illegible] and workshops, but I hope [illegible] inquiries now on hand have [illegible] rules by fuller regulations [illegible] p Act of 1901, and the question of applying these regulations to wharves and warehouses where the danger may arise will receive very careful consideration

Mr C. BATHURST: Does the right honourable gentleman realise the importance of gre[illegible] Home Office and the Board of [illegible] diseases which are common bo[illegible] MCKENNA: Yes, certainly.

THURSDAY, FEB. 19TH.

[illegible] Benefits to Women.

[illegible] the Secretary to the [illegible] uences of a threatened deficiency of Approved Societies under the National Insurance Act was the refusal of benefits by some societies to women who were certified as incapable of work owing to pregnancy; and, if so, what steps the Commissioners and the Government were taking in the matter.—Mr. WEDGWOOD BENN (who replied) said: Societies are responsibile for determining in the first instance whether an insured person claiming sickness benefit satisfies the conditions of Section 8 (i.) (c) of the Act of 1911 of being rendered incapable of work by specific disease or disablement. The Commissioners have no reason to think that societies are refusing benefit in cases where they consider that this condition is satisfied.

Mr. G. LOCKER-LAMPSON: Is the honourable gentleman aware that one of the medical referees has reported to the London Insurance Committee that this is being done?—Mr. WEDGWOOD BENN: No, sir. I shall be glad if the honourable gentleman will give me the statement made by the medical referee.

County Councils and the Treatment of Tuberculosis.

Replying to Mr. G. LOCKER-LAMPSON, Mr. HERBERT SAMUEL (President of the Local Government Board) said: The great majority of county councils and councils of county boroughs in England have submitted schemes for the provision of institutional treatment of tuberculosis, which treatment will be available for all classes of the community. In some few instances the schemes are at present limited to the provision of dispensary treatment. Six county councils out of 50 and seven councils of county boroughs out of the total of 75 have not yet submitted proposals, and the department is in communication with these authorities. I understand that proposals will shortly be submitted by the London County Council for providing additional sanatorium accommodation.

Mr. LOCKER-LAMPSON further asked whether in some districts no accommodation was available for advanced cases of tuberculosis among insured persons under the National Insurance Act.—Mr. HERBERT SAMUEL answered: In some districts there is insufficient accommodation at present for advanced cases of tuberculosis, but it will be gathered from the answer I have just given that county and county borough councils generally are taking steps to provide additional accommodation for such cases as part of their schemes for the institutional treatment of the disease in all classes of the community. The question is receiving my immediate attention.

Sir RANDOLF BAKER asked the right honourable gentleman to state how many county councils had built sanatoria since the coming into operation of the National Insurance Act and how many had taken no steps beyond the provision of dispensary treatment.—Mr. HERBERT SAMUEL replied: County councils are providing the necessary sanatorium accommodation in various ways. Nine county councils have already acquired existing buildings or provided new buildings, eight have acquired beds at existing institutions and are arranging for extensions to be provided for the use of the council, and ten have purchased or propose to purchase sites for the erection of new buildings. The other councils which propose to provide sanatorium accommodation as part of their schemes have not yet definitely decided in what way the accommodation shall be provided. Only seven of the councils have limited their schemes for the present to dispensary treatment.

Progressive Decline of the Birth-rate.

Sir WALTER ESSEX asked the Prime Minister whether he had in contemplation an inquiry by a Commission or otherwise into the progressive decline in the birth-rate in the United Kingdom.—Mr. ASQUITH answered: I understand that the matter is the subject of an inquiry on which the Local Government Board and the General Register Office are represented. It does not, therefore, seem that any further inquiry is necessary at present.

Returns on Industrial Poisoning.

Mr. NOEL BUXTON asked the Home Secretary whether the cases of industrial poisoning which appeared under the head of diseases of occupation in the Board of Trade *Labour Gazette* included only those furnished by the certifying surgeons; whether there were a certain number of cases in which the medical referee overrode the decision of the certifying surgeon; whether a corrected list would show a difference in the number of cases of industrial poisoning; whether the figures in the Board of Trade *Labour Gazette* were invalidated by the absence of any reference to the decisions of the medical referee; and whether the figures as modified by the medical referee's decision appeared in any other return.—Mr. MCKENNA replied: The returns of industrial poisoning to which the question refers include all cases whether reported by the certifying surgeon, by medical practitioners, or by occupiers. It occasionally happens that the certifying surgeon's opinion is subsequently overruled by the medical referee. So far as practicable allowance has been made for these cases in the annual return published in the January number of the *Gazette*, but the cases are so few as not to affect the substantial accuracy of the monthly returns.

Vaccination in the Navy.

Mr. WILLIAM THORNE asked the President of the Local Government Board whether the calf vaccine lymph used for the Navy was supplied by his department; whether he was aware that according to the annual reports of the health of the Navy the cases of cow-pox placed on the sick list in consequence of vaccination, which were 233 in 1903, had increased to 482 in 1909, to 688 in 1910, to 845 in 1911, and to 1255 in 1912; *whether he could give any explanation of these* increases of the ill effects of the operation; and whether he would consider [illegible] *vaccine lymph* [illegible] provement upo[illegible] replied: The a[illegible] is in the affir[illegible] question, I understand that the increase in the number of cases placed on the sick list is due chiefly to the much greater care now exercised in preventing the possibility of untoward occurrences following on vaccination. With this object in view men and boys are now in a greater number of cases recorded as being on the sick list after vaccination, and are consequently excused from duty for a few days. The character of the lymph supplied has no bearing on the question, and I see no reason for any alteration of the present procedure.

Hop Substitutes in Brewing.

Mr. HERBERT LEWIS (Parliamentary Secretary to the Local Government Board) informed Mr. ROWLANDS that it was not proposed to reintroduce this session the Bill to prohibit the use of hop substitutes in brewing.

MONDAY, FEB. 23RD.

Sanatorium Benefit.

Mr. WEDGWOOD BENN informed Mr. GODFREY LOCKER-LAMPSON that a return on the subject of the administration of sanatorium benefit was in course of preparation and would shortly be laid before the House.

Insured Persons and the Selection of Medical Men.

Replying to Mr. BUTCHER, Mr. WEDGWOOD BENN said: Under the Regulations issued under the National Insurance Act insured persons who had selected or had been assigned to a medical man in the course of last year are deemed to have selected that doctor for the current year unless they gave the notice required of their intention to make a fresh selection.

Insurance Drug Fund in Manchester.

Mr. GODFREY LOCKER-LAMPSON asked the Secretary to the Treasury whether there was a deficiency in the insurance drug fund in the Manchester district to the extent of about £16,000; and, if so, whether, in consequence, chemists on the panel had only been paid 50 per cent. of their accounts during the three latter months of 1913 and only about 27 per cent. for December, although it was one of their heaviest months; and what the Government proposed to do in the matter.—Mr. WEDGWOOD BENN replied: My right honourable friend is informed that the total sums already paid or in the course of being paid by way of advances amount to approximately 60 per cent. of the total amount of the accounts presented for this year. It is not, however, possible to estimate what further sums will be payable until those accounts have been scrutinised in accordance with the Regulations and the total sums available to the Insurance Committee for the purpose have been finally ascertained.

Distribution of Insurance Funds.

Colonel GREIG asked the Secretary to the Treasury whether the accumulated funds in the hands of the Insurance Committees in Scotland, arising from payments for medical benefit for insured persons who had not yet claimed or did not desire to claim a panel doctor, were to be distributed among the existing panel doctors or to be otherwise applicable and, if so, how; whether any regulation had been laid down in London or elsewhere for the application of such funds; and whether such regulation was applicable in Scotland.—Mr. WEDGWOOD BENN wrote in reply: Both in Scotland and elsewhere in Great Britain the whole of the sums available to a committee in respect of the responsibility for the treatment of those insured persons (including the persons referred to in the question) who have not been allowed or required to make their "own arrangements" and who have not selected an approved system or institution are payable, under the regulations and the agreements entered into between committees and doctors, to the doctors on the panel upon whom that responsibility devolves.

TUESDAY, FEB. 24TH.

Distribution of Insurance Funds.

Sir HENRY CRAIK asked the Secretary to the Treasury why the amount accruing in respect of insured persons who had not chosen a doctor, and had not been assigned to any doctor [illegible] by the London Insur- [illegible] ENN replied: My right [illegible] le matter of the distri- [illegible] ention of the London [illegible]

Excessive Sickness at Cradley.

[illegible] he [illegible] of [illegible] ald an inquiry into an alleged shortage of doctors in Cradley; that the inquiry disclosed excessive sickness; and that the doctors alleged at the inquiry tha[illegible] to help themselves out of the [illegible] solvency, were refusing to give [illegible] diseases, [illegible] and bron[illegible] thereby [illegible] proposed [illegible] the mem[illegible] insolvenc[illegible] no means of confirming the allegations and expressed no opinion upon them. The remaining part of the question does not therefore arise.

Machine-Skimmed Condensed Milk.

Mr. BARNSTON asked the President of the Local Government Board whether he intended to issue an order, under [illegible] 1907, regula- [illegible] whether [illegible] o recommendations contained in Dr. Coutts's Report to the Local Gove[illegible] foods [illegible] The [illegible] to is[illegible] to m[illegible]

WEDNESDAY, FEB. 25TH.

Allocation of Insured Persons.

Mr. BUTCHER asked the Secretary to the Treasury whether he was aware that the allocation of insured persons to a docto[illegible] giving [illegible] prise [illegible] tion which had been placed by the National Insurance Commissioners on Form 110/I.C. to the effect that a person who had been al[illegible] was deemed to [illegible] Commissioners [illegible] persons a circu[illegible] take if they wis[illegible] selected but to [illegible] WOOD BENN (w[illegible] now in force no allocation is carried out, except upon the application of insured persons themselves. It was open to insured persons who were allocated to doctors last year to change their doctor at the end of the year by giving the necessary notice, and every opportunity was taken of bringing to the knowledge of insured persons their rights in this respect. It is still open to insured persons who omitted to take the necessary steps last year and who now desire to change their doctor to do so by consent, and the medical card issued to insured persons already on the lists of doctors contains full instructions on the subject.

TUBERCULOSIS IN BRITISH GUIANA.

ACCORDING to the seventh annual report of the British Guiana Society for the Prevention and Treatment of Tuberculosis, the society's work in that district is bearing good fruit. A new memorial dispensary to King Edward VII. I
Government aid
measures recom
Conference on T

reduction in the past two years, the death-rate from phthisis per 1000 persons living from January to September, 1913, for the whole colony being 1·3. Gratuitous examination of all persons, irrespective of race, creed, colour, or financial status, has been afforded and attendance and medicine supplied free to those suffering from tuberculosis. The number of persons attending the dispensary has progressively increased from 828 in 1908 to 1277 in 1913, but the percentage found to be tuberculous has decreased from 14·5 in 1908 to 8·8 in 1913. The services of the lady visitors are highly commended.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1913 were given in THE LANCET of Dec. 27th, 1913.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1913 are now ready. Bound in cloth, gilt lettered, price 16*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

A Lecture
ON
GLYCOSURIA AND THE ALBUMINURIA OF ADOLESCENTS.

Delivered before the Brighton and Sussex Medico-Chirurgical Society on Feb. 5th, 1914,

BY SIR JAMES F. GOODHART, BART.,
M.D. ABERD., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

GLYCOSURIA.

MR. PRESIDENT AND GENTLEMEN,—Some months ago there appeared what was to me a very interesting paper[1] by Dr. D. M. Mackay, of Hull, upon Ocular Diseases occurring in Association with Diabetes Mellitus. In it I read: "There are serious affections of the *retina* which appear in *diabetes* ...... and it is this group of ocular complications that give gravity to the prognosis of diabetes." Again: "Diabetes is very frequently associated with the presence of arterio-sclerosis." I was alert at once because a responsive and critical chord was touched, which is equivalent to saying that I did not altogether agree with the writer's conclusions.

Forms and Course of Glycosuria.

We all know that sugar in the urine in young people means diabetes for the most part, and that it is a very serious matter; but we also know that a saccharine urine in those of advancing years by no means necessarily means diabetes, or, at any rate, that it is far less likely to be of the grave import that youth carries with it. There is, indeed, a sort of agreement abroad to restrict the term diabetes to the grave cases such as are for the most part found in the first half of life, and rather to designate as glycosuria the condition of later years. Nevertheless, I think the affinities of this latter form of malady are not so well recognised as they should be, nor do I think that the natural course of this form of glycosuria is sufficiently apprehended by many.

It hardly needs saying that a true diabetes, commencing as such, with all the classical symptoms, may, under treatment, carry on for many years, and even into the declining decades of existence. I am even strongly inclined to believe that all glycosurias, no matter at what time of life they occur, have something in common—an epileptiform or migrainous paroxysmalism. Therefore, whenever I find sugar in the urine of the comparatively young, even in traces, and further know that it has gone, I am never quite happy about it, for the glycosuria of early diabetes is frequently intermittent, and there is an inveteracy about the glycosuric habit that suggests the appropriateness of the term "epileptiform," for who can tell when it will come or when it has gone? Trousseau applied to angina pectoris, very fitly as I think, the term epileptiform neuralgia, and I borrow this comparison as being applicable to glycosuria, as well as to many another paroxysmal neurosis. But clinically there are two groups of the glycosuric, and you will understand me when I say we will exclude the diabetic and take such a case as the following.

Illustrative Cases.

A middle-aged man of, say, 50 to 60, in whom, on examining his urine, sugar is found. What is the environment, shall I say, of that condition? How has it come? What does it portend? How are you going to deal with it? I know, I say, that a large number of such people are said to be diabetic, and are treated with all the rigour of dietetic principle that such a state is supposed to demand. I want you all to agree with me that such cases in being so handled have got into the wrong pigeon-hole. The clinical history of such cases as this is usually: that the patient has been overworked; worried; has overrun his rest and holidays; a wife or child has been ill; politicians have been restless; nations have been spoiling for war; there have been panics, or nothing doing on the Exchange; affairs are not what they should be; and so on. Thus he has been worried, getting no exercise and ill-digesting his food, and not being quite well; often being giddy, headachy, or liverish; he goes to his doctor, who finds some sugar in his urine. It may be that a little dieting, a tonic, a holiday—and the sugar goes at once, but it will often go only to come again from time to time, and may even in the end have come to stay. But, as I think, the more important feature of these cases is: that in addition to the sugar you will perhaps find a trace of albumin; and then, on examining the pulse, the blood pressure is found to be excessive; in many a case, also, on listening to the heart sounds, there is evidence of labour and stress in their quality. Many of these people may have no albumin for some time, but if they be watched it will ultimately be there. Moreover, there is a tendency in most of them for the sugar to diminish in the course of years, and for the albumin to increase and to become the dominant feature in the case.

In 1901 I became acquainted with a lady, 74 years of age, because of an attack of profuse hæmaturia. She had recently lost her husband and was melancholic in a mild fashion. At that time I think there was no other disease, and we supposed the bleeding to be due to the passage of uric acid crystals. Not long after she developed glycosuria, the urine reaching a specific gravity of 1040. The sugar remained for several years, and before long albumin appeared in the urine also. Some three years before her death cataract developed, and one day she had an attack of giddiness and what was said to be a slight stroke, and her pulse, previously about 80, dropped to 40. She did not suffer in health materially from this condition, but the pulse never recovered its former rate. As time went on all the sugar disappeared from the urine, the albumin gradually increased to a large quantity, and she died from uræmia seven years after her attack of hæmaturia.

Retinal Changes.

So commonly have I seen some similar course of events that it has been an *obiter dictum* with me for many years that these people are not in danger so much from their glycosuria as such—with which alone indeed they may live many years, or to old age—as they are from the slowly maturing chronic Bright's disease, or what is now called arterial sclerosis. Now *these* are the cases that exhibit retinal changes with their glycosuria. With classical diabetes cataract of course occurs, but I am not familiar with retinal changes of any moment, and when I looked at Dr. Mackay's cases my opinion was confirmed. For example, the first case that he gives is that of "a man aged 66. In addition to incipient cataract in each lens there were in both retinæ many white patches, most marked round the macular regions, and in the right eye one or two minute hæmorrhages. After treatment by his own doctor for diabetes for four months he had a large fresh hæmorrhage in one of his eyes. In this case there was no albumin present, and therefore the condition was attributed to the sugar which was recognised for the first time after the retinitis had been detected." I doubt if this inference is warranted. Dr. Mackay's second case is a man of 62, who had been on strict diabetic diet for many years. He had hæmorrhages both near the disc and in other parts of the fundi, and white opacities. In this case the patient had had a considerable trace of albumin in his urine for six months in addition to the sugar. Another case is that of a man, age not stated, who gave a history of a stroke followed by a defect in his sight, apparently due to a cerebral lesion associated with glycosuria, and another in a man of 75 whose glycosuria had been present for years, but his doctor thought his diet had been too rigidly controlled and that the man's arteries had suffered in consequence.

---

[1] The Practitioner, May, 1913.

"*Gouty*" *Glycosuria.*

Gouty has this glycosuria of middle and old age been quite fitly called, and I repeat I do not doubt that many, perhaps all of you, are individually quite familiar with what I am saying, but so far as I remember Dr. Mitchell Bruce it is who, in his Lumleian lectures at the Royal College of Physicians of London, has most recently singled out these cases as a distinct clinical group, and lucidly dwells upon their importance. The syndrome, as it is now the fashion to say, is a very common one, it is distinct, and consequently an important one as regards its treatment. And here is the point. It is not necessary, it is probably not advisable to go for the sugar as sugar. I have known several such who were remarkably fond of sugar, and who, altogether against advice, would not, perhaps could not, restrain their love of lollypops, but who seemed to take no harm from their indulgence. Others there are who seem to derive great benefit from the relaxation of extreme regulations, and there are surely plenty of others whose sugar varies much from day to day, but without one being able to say that the variation depends upon the ingestion of the saccharine material that has preceded it.

Imperfect Metabolism.

I have said that I like the term "gouty" for this variety of glycosuria for the reason that it indicates correctly the tendency of the condition towards the gouty or granular kidney, or rather that state of the circulation with which a granular kidney is associated. What may be the relation between the sugar and the goutiness I must leave to the biochemist to decide. All I am able to say is that clinically there is an individuality that in early adult age may pass phosphates in quantity; to that will succeed a state of uric acid formation, in its early stages often combined with glycosuria; to this albuminuria and high blood pressure are prone to succeed; and the end of such is likely to be that of chronic Bright's disease. These cases then need to be treated with this probable course in view. I like to dwell upon these permutations of imperfect metabolism (as *I suppose they are*) in the urine, for it seems that on the one hand we make too much of them and on the other too little. We make too much of them when we regard their mere presence as that of a dangerous toxin, and immediately set to work to exorcise it by every possible means in our power; and so lose sight of the indications that such a presence gives of the individuality of the subject; we make too little of them when, exclusively directing our attention to our intakes as being the sources from which they emerge, we lose sight of them as *indications* of the improper working of the machine itself. It is the machine that is at fault in too many cases, not the fuel that is supplied to it, and there is a need not to damp down the fire but to set about to oil the various parts. Uric acid phosphaturia, oxaluria, glycosuria are, each and all, much more a question of the working of the machine than of the stuff that is put inside us, yet it seems impossible to get this into our heads or those of our patients, and we go on year after year on the same old round of uric acid, uric acid, uric acid. Glycosuria, as more obviously clothed in sombre garb, has especially fixed our attention, but I always wonder that phosphaturia and oxaluria have been so comparatively neglected, for I suspect that they are equally and fundamentally as instructive if they send us to the machinery, to our joints and harness, instead of being satisfied with cutting off our rhubarb and our spinach.

Treatment.

I cannot go into detail upon the treatment of such cases save to express my belief on two interesting questions: 1. That we have gone wrong these many years to my thinking in our slavish acceptation of the dictum of authority that the toxins of the imperfect metabolism of meat foods condition gout; as I will not allow sugar as sugar to be a supreme cause of glycosuria, so neither will I allow proteids or purins to be the prime movers in arterial sclerosis. I would not like to fasten goutiness on to any one food, for I believe the machine is mostly at fault, but I pay more attention myself to the imperfect metabolism of an excess of carbohydrates in leading eventually to such "goutiness" or what not as this. Nor are these cases, on the other hand, to be treated by stock methods of reducing tension. You cannot reduce tension in any persistent fashion, and if you could you would ofttimes kill the patient. Again I say, what is needed is to get at the chemical conditions underlying and determining the excess of pressure, and this is probably some gradually evolved habit of the working of the machine as a whole. No one who has ever given any thought to the matter could possibly think it likely that five grains of this or that could materially change so complex a working as the human machine except it were powerful enough to bring about a *bouleversement*—a collapse, in fact. Croton oil or elaterium may do this temporarily if you wish it. I have heard that it can be managed by electricity, and it is of interest from this point of view to note that when I myself have noted unusually sudden changes and variations of blood pressure they have occurred in cases of cerebral disease, and I am inclined to think that excessive blood pressure in the peripheral vessels is mostly thus spasmodic or hypertonic in origin, and that arterial sclerosis is its late effect. So in attempting to reduce blood pressure there may be many things to consider. Some machines there are that are always *hypertonic*; their nervous discharge or control can only work that way. They are the equivalents of noisy, uneasily running cars, and such decay early by excessive wear and tear. The stress may show itself in any organ such as the heredity or the individuality of the organism may dictate. In one it may be the brain, in another the heart, in another the liver or the kidney.

I do not doubt that those who hold that high blood pressure is due to some toxic state of the juices are in part right, but the toxin can be as well produced by the imperfect working of the machine as by a direct product introduced from without, and thus it happens in so many cases that the mere restriction of diet—the elements of diet—has so little effect. If I want to reduce the blood pressure in any given case I think I can do it best in a crude sort of way by ordering an exclusive diet of skim milk, or even of water. But by an actual limitation of food such as this one reverses the wheels of the machine and its currents, the stores of nutrient material redundant in the tissues are thus brought into use, and waste products are reconverted to useful purposes. In common parlance, such methods are dreaded as weakening the system. So in a sense they do. One would not under such a course ask, or expect, of a man a full day's labour. No more would one ask it of one under the effects of a strong purge, which is the more commonly adopted method of treatment for high pressure, and which brings about something of the same conditions—viz., a diminution of supplies, and from the sudden flux, more or less of a state of collapse for the time, which is equivalent, perhaps temporarily more than equivalent, to the sensation of weakness. But by the purging plan the effect is merely temporary, and even at that tends to become more so when frequently repeated, and thus less effective in its action. An occasional week on water would I suspect do many of us good, more even than the biannual venesection that used of old to obtain, and I suspect teaches the moral as regards such cases as led up to the subject that the way to deal with them in the future will be to put them under the skilled observation of the biochemist in an institution, where their intakes and outputs may be critically examined and analysed, and their food carefully adjusted to the capacity of their organs.

ADOLESCENT ALBUMINURIA.

And now let me turn to adolescent albuminuria—another matter of biochemistry. I know equally little about it, and want to learn of you. I am inclined to speak of it now as the paroxysmal albuminuria of the young. It is not ill-coupled with glycosuria, for each is both paroxysmal and functional. I do not propose to discuss it systematically, for you are all well familiar with it. It is an albuminuria of more or less, sometimes of large quantity, found in boys and youths from any age up to 19 or 20, and may be in young men up to 24 or 25 occasionally. It is not known to be anything like so frequent in girls, but that may be because the urine in them is not so often examined, and the periodical function is also there to interfere with, perhaps even to prevent, its occurrence.

This form of albuminuria occurs, in my experience, preponderatingly in overgrown and weedy youths, and in those, at any rate, who have been growing rapidly, and I think, too, in the food bolter, but there are frequent exceptions. It may be present in many a one of whom it is hard to say there is any ill-health. It sometimes disappears almost as soon as it is noticed, but more characteristically I think it comes and goes over a long period, maybe of months or years. And in such cases it is difficult to say that habits of life make any difference. In one case that I remember, as he was going to the seaside, a boy aged about 10 years was put under the medical care of Mr. W. M. Burgess, of Frinton, and allowed to bathe, and Mr. Burgess made careful observations on the urine. No appreciable difference could be noticed in the albuminuria one way or the other.

The quantity of albumin passed at any one time varies; usually it is not much, but it may amount to a very large precipitate. But the cardinal characteristic of the affection is that at one time of day—usually the first thing in the morning—there is only a trace or none, at another there may be a large quantity. One other feature I will mention, although I shall have to speak of it again, is that invariably in these cases a precipitate of globulin is obtained from the urine by adding a drop or two of strong acetic acid. This condition has been described at one time and another as cyclic, physiological, adolescent, or postural, albuminuria; and, given an undoubted case of the kind, it seems certain that it has no detrimental influence upon life, and there is no reason why it should penalise its subjects in the matter of work that they may be allowed to undertake. Yet it does so on all hands. No one in its presence will be accepted for any of the public services or large private banks, and no life will be accepted at any insurance office either. Albuminuria of any kind is still always looked at askance, as threatening Bright's disease, but in this case it is not so, the medical officers of all the great public schools are quite familiar with it, and know well that it passes off in due time and leaves no trace behind it. There must be any amount of experience to confirm this opinion.

Only a few weeks ago I saw a strong-looking young man aged 17 or so from one of our public schools, whose urine had been found to be albuminous by the doctor of his school, and quite rightly, as I am sure, passed by as unimportant. The boy's father unfortunately obtained other opinions, and then the risk of nephritis came into being, and the continuation of his school life and all his future became seriously in question. The case had, however, all the features of an adolescent albuminuria, and I am quite sure that it was right to let the youth pursue his school course, under the eye of the doctor, without interfering with it in any way.

Causation.

The condition is a most interesting one—mark I abstain from calling it a disease, and think of it as you will, it is difficult to say much that is positive as to the reason for its occurrence. It has not even found its way into the letter-box of oral sepsis. It has been called postural, for instance; because the albuminuria is often absent from the urine in the early morning, and only comes after the boy has risen from his bed. But I cannot think that the mere tipping a boy from his bed on to his feet can be sufficient to explain the appearance of albumin or justify the term postural. It is too mechanical to be probable. I cannot think that the upright posture has that to add to its many other present-day supposed delinquencies. Believing, as I do, that the clinical facts incontestably prove its harmless nature, they require, it seems to me, some physiological explanation, not a morbid one.

Now there are many relief or safety-valve processes in the body. A mitral murmur, for example, may be the result of disease or of a mere physiological relaxation in healthy tissues. The processes of thought are often curiously insane twixt sleeping and waking, and for many of us the darkest hour is just before the dawn. Yet not from disease, but from physiological inexactitude, want of sufficiently rapid accommodation, weakness as I have before allowed it to be in relation to food. And surely the explanation lies in this direction. It is in some way a metabolic matter. We have got our ideas of albuminuria too stereotyped into meaning inflammatory or at any rate congestive changes that way inclined, in the kidney. But I can recall to mind, and so can many of you, when there has been a sudden flux of large quantities of albumin which, suddenly coming, has as suddenly gone. Some of the puerperal albuminurias are cases in point. I have known such a flux replaced by one of uric acid, and as one thinks of such things the chemist in his laboratory comes to mind with his instantaneous precipitates and as sudden re-solutions; the passage of gases through his solutions and the rapid conversions and reconversions possible thereby, and methinks still to pin one's thoughts down solely to such processes as congestion and inflammation is to misread the whole trend of modern discovery and to confine ourselves somewhat obstinately to the dark and dawning ages of pathology. Even degeneration may savour too much of a necessarily structural change; but has it never struck you how much there is in renal change sometimes by way of rapidity, sometimes the reverse, that savours more of physiological effort, physiological retard, than of the cellular disturbances of disease?

Points in Diagnosis.

In this physiological albuminuria, this borderland perhaps, between natural function and disease, the amount passed is at times excessive, and that again and again in the same patient. Yet on any one day such a quantity would be present, say, at 11 A.M. and gone all but the barest trace at bedtime. I have known more than one such case treated for months as a bad case of renal nephritis, because the amount of albumin had so staggered the observer's judgment that no attempt had been made to gain further information, or do other than accept a too prevalent idea. Yet it is obvious that the mere fact of such a variation in the amount of albumin within a very few hours is sufficient to put the case out of the category or ordinary nephritis.

In every case of albuminuria in the young the first thing to do is to have specimens of urine for examination taken at intervals during the day and for several days consecutively. I always ask for four specimens: before rising, at 11 A.M., 3 P.M., and at bedtime. If in these several specimens any marked variation in the quantity is shown, from much to none, it is pretty certainly a case of the kind I am discussing. I like to see the albumin entirely absent from the urine at some time in the 24 hours, and then I feel sure of the diagnosis, but it by no means always vanishes entirely. Considerable variation within a few hours is the essential point, for this is obviously a feature incompatible, at any rate, with a pronounced organic disease. It is, of course, necessary to take all precautions, and to ascertain the absence of renal elements in the urine, other than casts of hyaline character, which, whatever be their meaning, from centrifugalised urine have seldom anything sinister in them.

There is also that other point, in the matter of diagnosis, that I wish to make, because it has been decidedly helpful to me, and may possibly be of importance from an etiological point of view. The albumin in these cases is, as in Bright's disease, largely a serum albumin—that is, an albumin that is precipitated on adding strong nitric acid to the cold urine and on boiling; but whereas in that disease it is almost invariably only serum albumin—I speak as a child in the matter of chemistry—in this albuminuria of the young there is as invariably nucleo-albumin or globulin as well. That is to say, on taking some of the urine and adding to it a drop of strong acetic acid there will come at the bottom of the tube a definite slight opalescence or milkiness from the precipitation of globulin. This precipitate mostly needs to be waited for a few seconds, and even then looked for, as it is generally but slight, but it is there, and sometimes it is there in abundance. I have used this test now hundreds of times, and whereas the reaction is quite uncommon in renal disease, it is seldom absent in physiological albuminuria. As perhaps weakening the value and significance of the test, but at the same time confirming the statement I have made, if it occur at all in anything approximating to renal inflammation, I think it is in the congestive conditions consequent upon back pressure and stasis, but even so its significance would seem to be that the condition precedent was not one of any advanced structural change. Nor does this admission weaken my hold upon the conviction that if in any young person, male or female, but possibly much more in males than females, you have to do with an albuminuria that shows great diurnal variations in quantity, is attended by no microscopical elements of renal disease, and is associated with a precipitate of globulin, that case is unassociated with any renal change; it will surely pass away as age advances, it is not likely to lead to renal disease, and it ought not to be allowed to penalise the constitution of anyone. I may add that the precipitation of globulin was abundant in the case already mentioned where there was a difference of opinion, and had much influence in fortifying me.

Comparison with Other Conditions.

The condition is a most perplexing one to unravel, but for that reason it is all the more interesting. In considering it, it may be as well to remember that there are other states that manifest themselves in very similar manner. The tides of urates, phosphates, oxalates, uric acid, and sugar each have resemblances. I have broached this subject earlier, and, indeed, uric acid and glycosuria are quite remarkable in this way. Uric acid, for example, may come on suddenly as a sort of storm, may remain for many months, and then vanish as suddenly as it came, without giving any obvious reason for thus behaving. But even more closely resembling adolescent albuminuria is the malady known as paroxysmal hæmoglobinuria. Here a man who calls himself well will suddenly feel a slight malaise or chilliness, and the next urine voided by him will be claret coloured or like porter. This urine is found to be loaded with albumin, and supplies a most copious precipitate of blood-coloured detritus, yet it contains no blood corpuscles of any moment; there are no casts or indication of renal disease; and the pigment is all due to the presence of methæmoglobin. What collection of signs could look worse for the integrity of the kidney? Yet they all vanish again within a few hours, the patient being no worse than he was before the attack; and the many examinations of such cases that have been made conclusively show that the kidney is structurally sound, and these cases never, so far as I know, eventuate in acute or chronic Bright's disease. The condition is indeed so sudden and evanescent that again it would seem to suggest some local chemical precipitation in the tubes of the liver or kidney, a local hæmolytic process, and perhaps, if so, it may furnish a suggestion of leucolysis for the albuminuria of adolescents, induced, say, by the hyperacidity of the night secretion and then brought to light by the tidal wave of the early day. There is no doubt that the morning urine, especially that passed after breakfast—when adolescent albuminuria is very prone to exhibit itself in a pronounced degree—is the sport of unstable function. It is then that a neutral urine with phosphates is prone to appear and to create great discomfort; I think uric acid also. Of sugar I am less certain; perhaps it and oxalates have a more diurnal distribution.

Circulatory Fluctuations.

Then the hypothesis of intermittent claudication is one that might conceivably have a good deal to say in explanation of paroxysmal albuminuria, or that, perhaps, and a tidal rhythm in conjunction. If we could see the peripheral circulation in the human taken as a whole as one can watch the blood flow in the frog's web, there would be witnessed recurring halts and retardations in the onward flow between one part and another, and this would be seen to apply not only to some small area, but also equally in larger measure to the entire vascular circuit, now here, now there, as controlled by nerves in common. We have only to think of it and one feels that it must be so, but we also know from instruments of precision that it is so. If means are taken to ascertain the blood pressure in arm, say, or leg, and having attained its average the subject is set to conduct some special train of thought, the manometer will at once show some local fall of pressure. The requirements of mental function demand an increase of supply, and reserves are called up automatically. Any number of examples of this physiological rule will occur to you, negative and positive. One of the earliest indications of failing nerve power is obstinate constipation; there are no supplies to meet the required expenditure. The proverbial shiver after a good dinner tells, I suppose, that much of one's energy of blood and nerve has gone elsewhere than to the skin for purposes of digestion, and that there is not quite enough to go round, and I have often thought that it might be a good gauge of the capacity of preacher or lecturer to set him to compose an address and take the temperature of his feet meanwhile. I doubt if many would talk twaddle if their feet grew cold as they write. Of this, no doubt, was born—and there is plenty to say for it—the old and almost forgotten method of treatment known as derivation, and perhaps counter-irritation also. Thinking thus one can readily see how congestion and stasis might occur, do occur, not as morbid states, but as temporarily recurring physiological conditions, and how even in such the natural osmotic processes might be interfered with *pro* and *con.*, how the normally adaptive changes of the nutrient juices might be arrested or altered; and how thus, especially under the sway of an incoming tide of function, a temporary globulinuria might appear. Moreover, fluxes of such sorts would certainly involve corresponding reflexes in the local areas of supply, and thus spasm as one of numerous results would follow.

One other point I would add: I have said that in most of these cases it is not a matter of ill-health with the subject. The condition is, perhaps, more likely to occur in states of relaxation or want of tone, and this is rather suggested by the fact, already stated, that in a very large proportion of my cases I have made a note that the boy was overgrown or had been rapidly growing within recent times, and I think it probable that in what should be a coördinate expansion and development of the body as a whole—mind and body—there is very often a want of correlation between the parts, and such as be fundamental and voracious in drawing supplies, the nervous and sexual centres, for example, may exact too much and depress the whole. The rhythmic character of the occurrence might be in part satisfied by some such supposition.

Doubtful Cases.

But having spoken somewhat dogmatically upon the innocent nature of paroxysmal albuminuria I must equally strongly insist that all such cases need a full examination before coming to a diagnosis. Medicine unfortunately does not admit of many unqualified assertions, perhaps of none, and you will meet now and then with a case where you must remain in doubt and upon which you must refuse to speak positively. For example, a boy, some 10 years old, was brought to me 15 months ago, who had had albuminuria for at least six months. He was of an exceedingly pallid tint and his tissues were flabby and unhealthy, and he gave me the impression of a child who had been bred up in a hothouse, but neither then nor at any previous time had he had any dropsy or, indeed, any evidence of serious illness. He had, of course, as was supposed to be right and proper for a child with renal disease, been shielded from every draught and chill, playmates and games were unknown to him, and he had been fed on large quantities of milk. The urine that was brought to me contained a very large quantity of albumin. I had four specimens of the day's urine sent to me several times, but, although there was some variability in the quantity from time to time, there was not so much as one is accustomed to find in these cases, and the albumin was never in any one specimen anywhere near being altogether absent. But the acetic acid precipitate was present in quantity, and there were no casts or other abnormal findings to be discovered in the urine. In such circumstances I was uncertain. By no means prepared to exclude renal disease, I was yet quite inclined to think it might be physiological, so we altered his diet, cutting off the quantity of milk he had been taking and giving him meat in an ordinary mixed diet. I do not know that I can yet say how the case will turn out, for there has been, and still is, albumin in all the specimens. I have examined two specimens of the boy's urine last week. That on rising is 1028, a perfectly healthy specimen to look at, but it contains a trace of albumin, and there is also present the acetic acid precipitate. An afternoon specimen is 1018, and gives similar reactions; but at any rate I can say this, that the boy is very much better in health, that he goes to school and seems quite well, and I am inclined to think that he will bear out the truth of the late Sir William Broadbent's remark, that to treat these cases as if they were cases of renal disease only makes them worse and converts some into chronic invalids.

From such cases let me turn to another of even less dubious nature. In February, 1911, I saw a boy of 13½, who was 5 feet 2½ inches in height—some 3 inches above the average—and 6 stones 2 pounds, about the average weight for his age. He was a poor specimen, more a girl than a boy, a good companion for adults, good at lessons, poor at games. He had a pallid face, and his urine contained a large quantity of albumin. There was but little to be got, but it was full of lithates as well as of albumin. I sent him home for further examination, and three specimens of urine were obtained; that at 8 A.M. was pale, clear, acid, specific gravity 1020, urea 3·3 per cent. Albumin only a very slight cloud. The deposit was small in amount, of flocculent mucus, with small numbers of epithelial cells, from the urinary passages, and a few leucocytes, but no blood, pus, casts, or crystals. The specimens passed at 11 and in the afternoon were neutral, the albumin being in each rather more than in the early morning one, the deposit giving similar results.

Now, having obtained the information that at one time the urine contained a large quantity of albumin and afterwards *a mere trace*, I suspect that I considered this a case of adolescent albuminuria, but unfortunately he did not come under medical observation again until this last autumn, when he was found to be generally œdematous, his urine to be solid with albumin, and the boy evidently ill with a very grave form of renal disease. The only history of illness that could be obtained was that of a bad throat early in the year, but from this he was supposed to have quite recovered. The case was in some respects peculiar, for he is a youth whose urine is always scanty; always contains quantities of lithates as well as the albumin; and his blood pressure is always low. I may add that his urine does not give the acetic acid precipitate.

Remarks on Nephritis.

One last word as to the bearing of much of what I have said upon the larger question of nephritis in general. These borderland cases do undoubtedly suggest that though certain groups of signs are clinically distinct enough, there is no hard-and-fast line—there could not be—between inexactitude of function and disease that reveals itself by structural change. Therefore, although I am suggesting that we must always take a liberal measure of the range of health, I would not on that account ignore its opposite, the play of disease. There is much in the pathology of the secreting structure of the kidney, whether acute or chronic, that may face either way, and that in doing so cannot but often raise the question, What is the best method of dealing with this or that individual *case*—as of old, I hardly know whether to say disease or patient—and I doubt not that you, as I am, are too often dissatisfied at the results of routine treatment. The prolonged period of rest in bed, the purging, the baths and other sudorifics, the attempt to reduce tension, the milk diet, the exclusion of all meat, purins, alcohol, and so on—each and all objects that may be good in due season—are often sadly deficient in good results, if indeed they be not sometimes productive of harm. And I suspect that each of us can recall many a case where a more generous outlook has been beneficial to the patient. There is no doubt, indeed, that nephritis varies much more between case and case than is generally allowed, the large red kidney, the large white one, and the granular kidney, are all definite enough, but why—to take only the more acute cases—is there a sudden onset in one; an insidious start in another? In one suppression of urine, in another polyuria? In one an always clear urine, in another a heavy uratic deposit, at the same time that there is much albumin? In one much albumin, in another little? In one high pressure, in another low? The same looking kidney more or less in all? It is clear that the gross lesion in the organ will not account for the variation in the particulars, and that you have to deal with the blood in one, the nervous system in another, the metabolism of a third, and so on; and there is perhaps no organ in the body of which it can be more appropriately said that to right it, or to give an opinion upon the chances of so doing, you must study the patient more than his disease.

The Hunterian Lectures
ON
INFANTILISM.

Delivered before the Royal College of Surgeons of England on Feb. 2nd and 4th, 1914,

By HASTINGS GILFORD, F.R.C.S. Eng.

LECTURE II.[1]

Delivered on Feb. 4th.

Mr. President, Ladies, and Gentlemen,—In my previous lecture I dwelt upon the subject of symptomatic infantilism and upon its main points of difference from essential infantilism, especially that form which is known as ateleiosis. In so doing it became obvious that the salient distinctive features of ateleiosis are in principle also characteristic of mutations in general. We now pass on to another of these characters of double significance.

Ateleiosis is Prone to be Associated with other Anomalies of Development.

It is recognised by biologists that mutations, or sports, of different kinds are apt to occur together in the same animal or plant. Ateleiosis also shows its character as a mutation in a similar way. Thus in two cases it was associated with multiple osteochondromata or exostoses, in one case with hyperplasia of the gums, in another with a persistent ductus arteriosus, and in others with malformation of the phalanges. In the skeleton of Bobby Fenwick there is a malformation of the mandible. Some have been associated with abnormal longevity, others with premature senility. Of these associated "sports" one of the most interesting is that of absence or of stumpiness of the phalanges, which has been recorded in at least four cases, for it reminds us of a similar state of affairs in brachydactyly, which is known to be hereditary and to occur in company with shortness of stature.

It might be expected of these associated mutations that they would be more likely to occur in organs which usually work together than in organs unrelated. But it is by no means certain that this is the case. Among plants variations crop up apparently irrespective of physiological relations, and generally speaking we can trace no more method in their distribution among animals. Yet there are exceptions to this irregularity, for it has been noticed that the organs which control growth or development seem to be specially selected for variation where variations are in fashion. At any rate, in plants when abrupt changes are of common occurrence the organs of sex are peculiarly liable to suffer, and in man we seem to trace a similar association.

---

[1] Lecture I. was published in The Lancet of Feb. 28th, 1914, p. 587.

Associated Anomalies in Organs of Sex.

Thus achondroplasia, epilepsy, imbecility, idiocy, deaf-mutism, obesity, genius, as well as myxœdema, cretinism, and many other abnormalities, are associated either with sexual repulsion, with lessened fecundity, or with downright sterility. This appears to be Nature's method of stamping out departures from the normal, especially if they be regressive or otherwise undesirable. It is not improbable that we can in this way account for asexual ateleiosis, which must be regarded as the culmination of a biological catastrophe.

Ateleiosis makes for sterility in many ways. Thus in the first place, except to the lovers of the odd or the marvellous, such very small people are not attractive, so that they are not so likely to get married as are normal individuals. Schmolch,[2] in referring to ateleiosis appearing in no less than 9 members of one stock, says that the people of the district were disinclined to marry even the normal members lest their children should be dwarfs.

It is probable also that the marriages of sexual ateleiotics with normal individuals are less fertile than is usual with people of ordinary stature, though we have no proof. But when two sexual ateleiotics marry there seems no reason to doubt that there is a decline of fecundity. It is true that out of the few cases recorded in one, that of the Gibson family, there were 9 children, 5 of whom grew up and were of normal size; and in another, that of the Skinners, there were no less than 14 children, all well grown and healthy, and in both of these cases the description of the parents is sufficient to stamp them as ateleiotics. On the other hand, diminished fertility is expressed, still more emphatically, in the frequency with which we read of greatly delayed development of the sex organs. This, as we already have noticed, is met with in all degrees, from mere scantiness of facial hair to complete sexual arrest dating from early fœtal life.

The most probable explanation of these varying relations of sexual to somatic development is that the local anomaly of sex development is either of a satellite nature or is reciprocal, and is the outcome of their normal correlation. Complete or conspicuous arrest of sex development is probably a mutation; but the lesser degrees of sexual defect may be due to the influence of correlation such as was referred to in my first lecture.

Associated Thyroid Insufficiency.

Another organ which, under ordinary circumstances, is in intimate relations with general development is the thyroid gland, and we know that it was Brissaud's opinion that the type of infantilism, of which most cases of ateleiosis are examples, is in reality the result of thyroid hypoplasia. And there is much to be said for this view, for often there is a slight puffiness or doughiness of the face, a peculiar yellowish waxiness of the complexion, and occasionally a pink tinge, eminently suggestive of myxœdema. It is not unlikely that these symptoms are actually produced by thyroid inadequacy, for it is sometimes difficult to make sure of the presence of the thyroid gland.

It is certain, too, that there are cases in which it is not easy to decide as to whether one has to deal with simple cretinism or *myxœdème fruste*, or with ateleiosis combined with cretinism. I myself have seen a case of this sort which was very puzzling, and of which I now show a photograph. It seemed quite impossible to say whether there was more ateleiosis or more cretinism in its composition. I was unfortunately unable to solve this problem by giving thyroid artificially.

Some of these cases may be examples of *myxœdème fruste*, but it is highly probable that many are, as they appear to be, examples of ateleiosis with secondary cretinoid symptoms or with actual cretinism. The explanation of such cases is that just as the sex organs are closely bound up with developmental affairs, so also is the thyroid gland, and that as we have all degrees of sexual incompleteness occurring in association with ateleiosis, so are there all degrees of thyroid insufficiency.

Associated Abnormalities of the Pituitary Gland.

A third endocrine organ intimately concerned with general development is the pituitary gland. But it will not do to assume that every case of infantilism in which there is a tumour of the hypophysis, or enlargement or smallness of its sella, as revealed by X rays, is necessarily pituitary infantilism. We have no more reason to come to this conclusion than we have to conclude that every case of asexual ateleiosis is the direct result of want of development of the sex organs, or that ateleiosis with symptoms of thyroid inadequacy is no more than primary cretinism. It is highly probable that just as pituitary hypoplasia may account for its own special type of infantilism, so also the pronounced form of infantilism with sexual hypoplasia which is sexual ateleiosis may occasionally be associated with some correlated defect or abnormality of the pituitary gland. If the sex organs and thyroid gland be sometimes involved in the biological misfortune of ateleiosis, we can hardly suppose that the pituitary body, whose functions are so closely bound up with the function of these same organs and with general development, will be exempt from such secondary disturbance. In one of Ettore Levi's[3] cases, before referred to, we seem to have an example of such secondary implication of the pituitary gland.

There were two sisters, one of whom grew normally until her tenth year, the other until her ninth year, when growth stopped or was checked. The former was 20½ years of age and 133 cm. high, and the latter 15½ years and 130 cm. high when described by Levi. In both cases the development resembled that which is usually met with in girls of between 10 and 11 years of age, that is at the height to which they had attained. They were therefore of the Lorain type. Yet apparently they were not examples of symptomatic infantilism, for no cause was found, and the cessation of development seems to have been very abrupt and definite. They were not apparently in a state of debility such as might account for their condition; and, above all, the occurrence of heredity, apart from any common cause, shows that the infantilism was of the nature of a mutation. In both cases there was sexual immaturity. The sella turcica of the of men of more anthropoid type, who, like the chimpanzee, orang, and gorilla, had branched off from the leading stock which constituted primitive man. At any rate, among the bones of animals and the flint implements of later palæolithic origin have been found the skeletons or skulls of a much more elegantly formed, shorter people, and there is plenty of evidence that men of this latter type at one time inhabited vast tracts of Europe, Asia, and Africa, where they are now extinct.

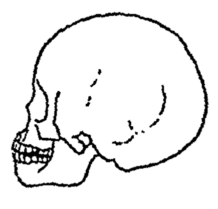
---

[2] See Eugenics Laboratory Memoirs, Treasury of Human Inheritance, Parts VII. and VIII., Section XV. A, Dwarfism. Virchow's Archiv, Band clxxxvii., S. 105, 1907.

[3] Nouvelle Iconographie de la Salpêtrière, tome xxi., pp. 297, 421, 1908.

Two skeletons of dwarfs of the Aurignacian age found in a cave at Mentone may be given as examples. These skulls, one of an old woman and the other of a boy of about 17 (Fig. 2), are of negroid character and have been shown by Pruner-Bey to be remarkably like those of modern Bushmen. The height of the woman's skeleton is about 1580 mm. and of the boy's 1540 mm., the present-day Bushman having a mean of 1530 mm.[11] It will be noticed in the pictures of the skull of the woman, which is compared by Professor Sollas with that of an adult Bushman, that the Aurignacian skull is still more infantile in its characters than is that of the Bushman, even if we take into consideration that it is the skull of a woman. The face is shorter, the body of the mandible being especially shallow, the muscular prominences less pronounced, the forehead more bulging, the nasal bone shorter, the cranium more rounded and almost devoid of character.

FIG. 2.



Palæolithic skull of Aurignacian youth, aged about 17, showing infantile and negroid characters. Infantile or childish features are shown in the relative proportions of the skull and face, the shape of the skull, the prominence of the forehead, the smallness of the nose, the size of the eye sockets, and in the character of its margins and of the brows. (Outline of Figure from "Les Grottes de Grimaldi," par R. Verneau, *L'Anthropologie*, tome xvii., p. 291.)

There are some interesting fossil bones of one of these dwarf races in this museum. They were found in 1910 by Colonel Willoughby Verner in a cave near Gibraltar and were alluded to by Professor Keith in his Hunterian lecture of 1911.[12] The latter regarded the thigh bone as "quite unlike any human thigh bone now known" and as of considerable antiquity. Dr. Duckworth[13] is of the opinion that the femur resembles those of the Aurignacian (palæolithic) dwarfs and of modern Bushmen and Andaman islanders.

3. *Prehistoric Drawings of the Human Figure.*

Fortunately, some of these dwarf peoples were given to drawing and painting, and a few of their incised drawings are still extant; and it is significant that these drawings or carvings rarely represent men of the coarse, long-limbed, beetle-browed, muscular type, but almost invariably of the short-limbed, big-headed type. Moreover, though some of them are fat or in a state of pregnancy, they are usually more or less elegantly formed and either with rounded outlines or else of slender build. Yet they are evidently not people of any civilisation, for the figures are always naked, and three of them are depicted as hairy. Some are evidently drawn by practised draughtsmen. Indeed, so much ability is shown that we attach all the more importance to their proportions, although in two cases the limbs are so exceedi[illegible] that they [illegible] functionally inadequat[illegible]. Figs. 3, [illegible] adult human figures o[illegible] origin [illegible] infantile characters.

FIG. 3.

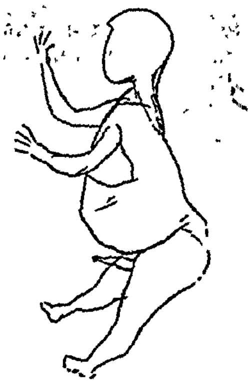


FIG. 4.

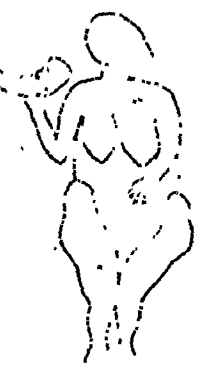

FIG. 5.

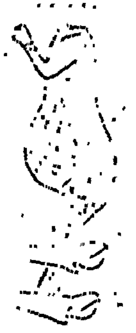

FIG. 3.—From an [illegible] (From "Sur les [illegible] Paléolithique," p[illegible] p. 421, 1910.)

FIG. 4.—Outline d[illegible] Department of t[illegible] at least 15,000 t[illegible] earliest known s[illegible] Figuration Hu[illegible] xxiii., p. 129, 19[illegible]

FIG. 5.—The "F[illegible] pregnant wom[illegible] hair on the [illegible] historique," [illegible]

These fig[illegible] remote pr[illegible] Compariso[illegible] Magdalen[illegible] human figures, [illegible] of short peoples of back[illegible] In other cases cave-drawn figures [illegible] men of highly conventional type have been reg[illegible] as akin to those drawn by the Bushmen of South Africa. This idea has been elaborat[illegible] by Professor Sollas in his "Ancien[illegible] their Modern Representatives," w[illegible] out many striking similarities b[illegible] and drawings of the Aurignacian [illegible] present-day Bushmen.

4. *Tradition.*

Pictures are not the only trace[illegible] left behind by these prehistoric [illegible] thing may also be gathered fro[illegible] form of folk stories or of [illegible] collected from many differen[illegible] extraordinarily similar that it [illegible] them over as of no value, the[illegible] being by itself valuable evi[illegible] founded upon facts. These [illegible] giants, but as a rule to dw[illegible] names of pixies, kobolds, fai[illegible] nisses, trolls, elves, and little [illegible] were characterised by a mix[illegible] ness and simplicity, where[illegible] only big, but dull-witted, [illegible] tastes. often cannibals, and [illegible] people.

The sort of knowledge which we ge[illegible] stories and fairy tales all tends to bear out evidence showing that in some remote prehistoric times there were few parts of the earth's surface which were not inhabited by dwarf races. Moreover, the manners, intelligence, and even the appearance of these little people have been handed down by this same kind of tradition. Thus, according to Mr. Croker,[14] an "elf" appears like a beautiful child a few years old, delicate and well-shaped; the Scotch and Welsh legends describe him decidedly in this manner. Yet they were not all of one kind, for "in the tradition of these fairies they are described at the same time as beautiful and as old and ugly. The dwarf too has the infant form, but is aged and disagreeable in appearance." Mr. Craigie[15] says that dwarfs among the Scandinavians "are short and thick, beardless, but not at all ugly. They are as big as children or babies. Nisses are no larger than little children." They "are *only 3 or 4 feet high, with big clumsy heads, broad* faces, big round noses, and red hair."

[12] THE LANCET, 1911, vol. i., p. 722.

[13] Prehistoric Man, W. L. H. Duckworth, p. 49.

In regard to the manners and customs of these dwarf people we are told that they were fond of dancing, of music, of processions. They were active, roguish, good-natured, capricious; a combination of good and evil, of duplicity and sincerity; sometimes generous and obliging, at others in the highest degree vindictive or malicious. Though fond of teasing, of making game of people, they would not suffer themselves to be laughed at nor permit any retaliation.

In short, in nearly all countries we find these little people represented as not only with the size and proportions of children, but also as showing childish traits and the disposition, tastes, the mixed simplicity and astuteness so characteristic of childhood. In a Chinese picture reproduced by Moseley,[16] some of them with the proportions of infants or young children are represented walking arm-in-arm. The work from which this picture is derived is supposed to date back to 2205 B.C.

Mr. E. S. Hartland in his "Science of Fairy Tales" (p. 345) says that "the myths of nations all over the world follow one general law and display common characteristics," and that "all these folk *stories are built upon the same general plan*; the same backbone of thought runs through them; and between them all there is no greater divergence than that which in the physical realm separates mammal from bird or bird from reptile. It is inevitable to conclude that even the most recently discovered folk tale of them has come to us from a distant period when our forefathers were in the same rude state as Dyaks and South Sea Islanders."

Another great ethnical authority, Mr. E. B. Tylor,[17] states, that these tales of dwarfs "are connected with traditions of real indigenous or hostile tribes is settled beyond question by the evidence brought forward by Grimm, Nilsson, and Hannsch."

5. *People in a State of Racial Infantilism.*

We have already referred to the dwarf races which still exist in different parts of Asia and Africa. Some apparently are of negroid origin, others show Mongolian affinities. There is good reason to believe that they represent peoples in a state of racial stagnation or infantilism. The causes calculated to produce racial infantilism would be of a regressive or depressing character. In the case of these racial or phyletic dwarfs there exists a depressing environment quite sufficient to account for the extreme sluggishness of their evolution. This is constituted by the great gloomy arboreal forest in the shades of which so many of these dwarfs live. And similarly with the Bushmen and other dwarf races which are subjected to hard living in deserts or mountains.

Kollmann's view is that these ethnic dwarf peoples are the direct and but little altered descendants of the palæolithic dwarfs who at one time were spread over the greater part of the world and whose drawings and bones are found here and there in Europe. They represent the dwarfs of the caves and the woods, who at one time danced in the moonlight in most of the countries of Europe, Africa, and Asia and who were the origin of the legendary tales of little people which exist in all *nations*.

Sir William Flower[18] termed these ethnic dwarfs "living fossils" and remarked on their round heads, which are contrasted with the longer heads of the living races around them, and also on the "almost infantile appearance" of some dwarf crania.

There is much diversity in the different accounts of these dwarfs. They are often described as like monkeys, and are even termed "monkey people" by their neighbours. Some resemble children in their proportions. They then have large heads, rounded foreheads, high shoulders, short lower limbs, protuberant abdomens, small hands and feet, and short flat infantile faces. Their noses are sunken at the root. Like children, they show remarkable uniformity in their physiognomies. Facial hair is scanty, yet among some tribes the whole body is apt to be clothed with a sparse or more or less thick crop of reddish hair. De Quatrefages says that two full-grown Akkas brought to Europe in 1873 were by some of those who examined them regarded as children. De Quatrefages[19] says of their dispositions and habits that "the general character of the two Akkas has remained sensitive, impulsive, and recalls that of our children. They love to play; *their movements are quick*; when they walk they only go at quick step." It is, of course, among women in especial that the infantile characters predominate, and Ratzel[20] figures an African woman of mature development, who, apart from her colour, the character of her hair, and her sexual features, would do for the picture of a European child. It has been noticed that the pygmy pelvis tends to approach the infantile form. In other instances the proportions are *those of ordinary adults. This* was the case, for example, with two Akka skeletons, now in the Natural History Museum, given by Emin Pasha and described by Sir William Flower. These and some other Central African dwarfs, though childish in some respects, are in the main of adult proportions.

Flower said of these dwarfs that "they are obviously negroes of a special type and bear much the same relation to the larger long-headed African negroes that the negritos bear to their long-headed Melanesian neighbours." And this view is also held by Professor Keith, who believes that the dwarf races are in reality offshoots from the neighbouring races of bigger people.

There are, therefore, two ways of looking at these ethnic dwarfs. In the one they are regarded as never having arrived at a higher point of evolution. In the other it is supposed that they are derived locally from neighbouring races of ordinary stature. But according to the modern views of genetics such a change would not take place by a series of smaller degrees of variation, but would be much more likely to start suddenly by mutation. And the kind of mutation calculated to reduce people from a bigger and more mature type to a smaller and less developed would be a regressive variation. It would, in short, be of the nature of the mutation which we suppose is ateleiosis.

[20] The History of Mankind, transl. Butler, Div. K, Book iii., p. 302.

In Europe, where racial standards are constantly improving, such a regressive sport as ateleiosis meets with a cold reception, for it is in discord with the circumstances of our civilisation. It therefore soon becomes extinct. But a similar regression to a dwarf type occurring among nations themselves regressive and surrounded by conditions unfavourable to progress would be much more likely to be fertile and to survive. And the point I wish to accentuate is that such regressive mutations necessarily tend to reproduce characters distinctive of an earlier evolutionary type. A regressive variation is a reversive variation.

If we sum up the evidence afforded by these ethnic dwarfs of Asia and Africa we observe that within restricted limits they exhibit great diversity of form. Some show many childish or infantile features, others are of more adult type. But on the whole their height, proportions, history, conduct, tastes are in favour of the view that they are indeed the present-day representatives of man in the infantile stage of his evolution, but modified by circumstances. It is hardly conceivable that any animal should remain for untold ages exactly stationary, marking time in his evolution. It is much more likely that changes have slowly gone on. And these changes would tend to bring the pygmies into line with neighbouring races, some of them being in the direction of a more adult type of figure, others in that of negroid or other characters suitable to their habitat.

Much interesting information about "The Pygmy and Negro Races of Africa" was given here in a Hunterian Lecture by Dr. F. C. Shrubsall[21] eight years ago.

Very little seems to be known of the children of these negrito and negrillo races. But there is an important specimen in this museum which bears upon the subject. It is that of a newly born child from one of the Central African dwarfs. This child weighed 5 lb. 12 oz. It was therefore about 1 lb. under the weight of a normal European baby. Yet it was apparently an unusually big negrillo baby if we may judge from the fact that it owed its death to the difficulties which attended its birth.

6. *Modern Children.*

We now come to the evidence furnished by contemporary undeveloped man. It is now regarded as an established truth that the young child playing with his Noah's ark, with bows and arrows, delighting in the rhythm of music and of dancing, fond of all sorts of living animals, wild and tame, eager for country walks to gather fruit and birds' eggs from the hedges, enjoying the glow and crackle of bonfires and in terror of the dark, derives his tastes from his remote ancestors who lived at a time of evolution which corresponded with the childhood period of individual development. His innate conservatism, his vivid imagination, his especial liking for stories of wild life and adventure, of uninhabited islands, of fairy tales, are full of significance.

All this is, of course, well known to everyone here and need not be dwelt upon, but what is important to my subject is that the evidence of our descent from a savage type of man is not exclusively functional. All these savage traits must have a physical basis. This is as certain as that a certain kind of structure is inseparably connected with the function of urinary secretion, another kind with the production of bile. It is but natural to suppose that in a general way the type of being which reproduces the ways of our palæolithic ancestors must also to a similar degree reproduce his structure. This will, of course, have changed from the orginal type during the ages, but there is no reason to suppose that this modification will be more of form than of function.

We must regard the child as the outcome of two sets of circumstances. The one set, prehistoric, tends to reproduce the characters of primitive, undeveloped man; the other, contemporary, is partly pre-natal and partly post-natal. He is the original wild man suitably moulded for existence in the uterus and as a baby and child. He is the creature of heredity adapted to a modern environment.

I am quite aware that this view of the phylogeny of man goes no further than to the fringe of the matter, and that its statement is one-sided. But I am emboldened to adopt it because I know that it has already been advocated by Kollmann and by many other anthropologists. Moreover, I can hardly do otherwise, for it is the logical outcome of the biological method of dealing with my subject. I feel myself carried inevitably along to the conclusion to which I have arrived, and can see no other way of accounting for infantilism. This biological conception of ateleiosis may possibly throw light on some of its characters difficult to explain. It may account for the way in which ateleiosis not only perpetuates infantile features but exaggerates them. In other words, the growth which creeps on so tardily after ateleiosis has set in, instead of tending to obliterate the infantilism accentuates it. And this fact must needs be regarded as much in favour of the reversion theory. Thus, the exceedingly short limbs of some ateleiotics forcibly remind us of the limbs of the carved drawings of Aurignacian origin. The noses also of some sexual ateleiotics are so excessively sunken at the bridge as to look pinched in or puckered, and this same feature may be noticed in some of the Mid-African dwarfs.

Another character noticed by Rischbieth as hitherto unexplainable is the peculiar yellowish tinge so often seen in ateleiotics. Is it conceivable that this represents a reversion to the skin pigmentation of primitive man? Schweinfurth compared the colour of the Akkas to that of coffee slightly roasted; Bushmen are of a light yellow tinge.

Yet another fact of possible biological significance, also referred to in the "Treasury of Human Inheritance" (p. 508), is the occasional occurrence of ateleiosis in people of a similar name possibly coming from the same stock but not known to be related. The particular instance given in the "Treasury" is that of the two Lehnens, one of whom, Jacob, was a celebrated painter born at Hinterweiler in the province of Treves in 1802[22] and who died at Coblenz in 1847 at the age of 45. The other, Peter Lehnen, was described by Schaaffhausen. He died at Coblenz at the age of 61 in 1868. No connexion can be traced between these two cases, both undoubtedly ateleiotic. Nothing is said about the occurrence of dwarfism in others of

---

THE LANCET, 1906, vol. i., pp. 983, 1050, 1133.

[22] The particulars are from "Les Nains et les Géants," by Edouard Garnier, p. 238.

Jacob's family, but Peter was one of a family of nine, four of whom were dwarfs, he being the eldest. Though it is not possible to trace any direct connexion, it is in the highest degree improbable that there is not some bond of relationship between them, though it may be remote.

We also notice that the Magri family came from the province of Ferrara in Italy and the Magro family from Sicily, both being examples of hereditary ateleiosis. Possibly these two families were offshoots from one stem. For it is characteristic of mutations that they should be latent, breaking out in perhaps widely separated branches from the same stock.

CONCLUSIONS AS TO GENERAL INFANTILISM.

We are now in a position to make a general statement as to the nature and origin of general infantilism. General infantilism is a variation of the process of normal development whereby it is seriously hindered at some stage prior to the appearance of puberty. There are two main biological divisions.

The one is a fluctuation. In other words, the appearance of the infantilism is determined by two factors, the one an inherent tendency for development to be curtailed, the other an environment, or its equivalent, which facilitates or accentuates the change. The variation is of a regressive character; hence the environment which is congenial to its appearance is itself of a regressive or depressive kind, and consists in the toxins or in the presence within the body of an imperfect or diseased organ which by correlation exerts an injurious influence upon the body as a whole. Or the depressive agency is exerted in a secondary manner through a secretion from one of the organs which preside over development. This form of infantilism is therefore symptomatic. Symptomatic infantilism being the outcome of a milder degree of variation is the less striking of the two forms, is usually of the Lorain type, and often terminates in ordinary dwarfism.

The other form of variation is more emphatic, for it tends to delay development to a still greater degree. It is so strong that it is in no way dependent upon the action of environment and is hereditary. It is a mutation, and like all mutations is prone to be accompanied by corresponding mutations in other directions. One of the most notable is that which affects the reproductive organs, stopping their development and tending, therefore, automatically to its own extinction. This important feature serves to divide mutational infantilism into two kinds—the sexual and the asexual. It must be recognised, however, that these merge one into the other, there being all sorts of gradations between them. Of infantilism as a mutation, or essential infantilism, there are two forms, ateleiosis and progeria. Either of these may appear at any age before puberty, giving rise to important differences in their appearance. Ateleiosis may therefore be divided into three classes, of which the first or most pronounced class originates in fœtal life, the second in infancy, and the third during childhood.

Ateleiosis being a mutation of a regressive kind virtually stops the development of the human being at a stage which corresponds to a similar stage in his evolution. Hence ateleiotics of the first class are often imbecile or lack intelligence. Those of the second class bear comparison with all that we know of certain short human beings who lived in the early Stone Age. The evidence we possess tends to show that palæolithic man varied widely in stature, in intelligence, and in many other characters. Yet he may be divided into two great classes. One was decadent, tending to the reproduction of the characters of a far earlier type of brute ancestry. Primitive man of this stamp was, as a rule, big-boned, coarse, muscular, brutal. Generally speaking, his cranial and facial characters were of the simian type. This same degenerate appearance tends to find expression in contemporary man under degenerating conditions. It is expressed in the natives of Australia and New Guinea. Traces of it are seen in the coarsening of the physiognomy, the drooping of the shoulders, the overhanging eyebrows of old age. It is sometimes markedly shown in that pathological degeneration which sweeps over the whole body in acromegaly and loosens the restraints of growth and development in nearly every organ of the body. It is manifested in the lowering of the brows, prominent jaws, coarse features, furtive expression, and stooping attitude of the criminal, and in the corrugated brows and clenched and exposed teeth of cruelty, brutality, and passion.

The second type of prehistoric man may be denominated the child type. The evidence that our descent has been from smaller to bigger and not from bigger to smaller is indicated in many ways. Man in his development recapitulates his ancestry. There are many traits in the life of a child which can only be explained as reminiscent of a corresponding stage in his evolution, and these functional evidences must correspond in some degree with an appropriate formation. There must be some fitness between the bodily architecture and the uses to which that body is put. The form of a child must be in many ways reminiscent of that of the savage ancestor who has handed down to him his social and ethical peculiarities. Evidence of this kind meets with support from tradition, which also points very clearly to the previous inhabitants of the earth having been of the big and degenerate type on the one hand, and of the small, child type on the other. Figures carved by these long-ago ancestors tend to confirm this impression.

Lastly, in certain inhospitable parts of the earth's surface, such as are calculated to stagnate development, there exist here and there races of dwarfs, many of whom approach the child in size and proportions. The nature of their surroundings, the character of their weapons, their tastes, habits, psychological characters, the contrast they present with their bigger neighbours, all tend to give the impression that they represent remnants of numerous dwarf peoples who at one time spread over the greater part of the earth's surface.

All this evidence points to the conclusion that the immature human being, stopped in his somatic development while still a child, but sexually perfect, reproduces in a general way the characters of his ancestors of the early Stone Age.

INFANTILISM OF SENILE TYPE.

It has been observed that among the secondary eccentricities of development which accompany ateleiosis we meet with some which affect longevity. Although it is probable that ateleiosis, as a rule, is not conducive to a normal duration of life, there are a good many cases on record, having regard to the rarity of this form of infantilism, in which life has continued well beyond the normal three score years and ten. So that we naturally ask whether it is right to regard ateleiosis as a disorder, seeing that even in its characteristic form it may rather protract than curtail the general curve of development. But as with other characters of ateleiosis, we have to fix our attention upon the condition as a whole rather than to select special cases. We can set off against these examples of abnormal longevity an equal number showing premature old age. Both extremes are abnormal and serve to impress us with the abnormality of ateleiosis itself.

Among the cases of premature senile decay or senilism which have supervened upon the infantilism of ateleiosis some have been of a very conspicuous character. One of these, described by the late Dr. Ransom,[23] is a very good example of the importance of not attributing infantilism to pituitary defect unless the evidence is pretty conclusive. For in this case the symptoms during life were exceedingly suggestive of a pituitary origin. The patient was a single woman, aged 27, who had left school at 12 owing to constant headache. There had been symptoms of diabetes for two years. She was 1307 mm. in height, equal to that of a child aged 10½ years. The face was said to be "juvenile, resembling that of a girl of 11 or 12, but also pinched and worn and with a suggestion of age." She was greatly emaciated. After death there were found "premature senile changes—e.g., atheroma, endarteritis, fibrosis of the thyroid, pancreas, spleen, mesenteric glands, and pituitary body." Mr. J. H. Targett pronounced the fibrosis of the pancreas to be "peculiar and not like the cirrhosis of diabetes." "The pituitary body was normal to the naked eye. Under the microscope there was a well-marked increase of fibrous tissue in the glandular portion, but on the whole the appearance of the gland cells was normal." "There was marked underdevelopment of the generative organs. Neither ovaries nor testis could be found, and the uterus was represented by a small T-shaped body, one inch long by one-third of an inch broad." Dr. Ransom regarded it as a case of asexual ateleiosis showing premature senile changes. And with that view I think we must agree. It seems to have been of the childish, or third, class.

I have myself elsewhere described other cases of infantilism of the senile type.[24] One of these was the celebrated French dwarf Bébé, who died from senile decay at the age of 22½ years. Here the occurrence of microcephaly and of syphilitic changes makes it difficult to determine the exact nature of the infantilism upon which the senilism supervened. Although as a rule the senilism is secondary to ateleiosis, as in Dr. Ransom's case and in one of my cases, it sometimes arises simultaneously with the infantilism, and this is progeria.

PROGERIA.[25]

Although progeria was described in 1886 apparently only three undoubted examples have been recorded. The late Sir Jonathan Hutchinson was the first to give an account of a case[26] in 1886. I myself followed with another in 1902 and four years ago Dr. Variot and Dr. Pironneau,[27] of Paris, described a third case. There are also the more important bones, including the complete skull, of an example of progeria in this museum, fully described by Professor Keith[28] last year. The first two were in males, one of whom died at 17 and the other at 18, both from senile decay. Variot's case in a female is, I believe, still alive. To-day I am able, through the kindness of Dr. Arthur Davies, to mention a fourth case, in an adult man, not yet described.

I do not propose to enter into the details of this extraordinary malady. I need only state that it is characterised by profound infantilism running side by side with premature senile decay or senilism. Although it differs widely in its manifestations from ateleiosis, progeria is also an essential infantilism and can be traced to no definite cause. The characters of this infantilism are graphically brought out in Professor Keith's article in THE LANCET. He there makes a searching and convincing comparison between the skeletons of progeria and of acromegaly, between those of progeria and of ateleiosis, and between the two last and a normal skeleton. This comparison tends irresistibly to the conclusion tha[illegible] to acromegaly. Moreover, he [illegible] sible that ateleiosis stands in the same relationship to progeria as giantism stands to acromegaly." M. Variot and M. Pironneau are, on the other hand, inclined to regard the series of changes in progeria as the result of suprarenal inadequacy.

The above-mentioned three cases were extraordinarily similar. The photographs which I have seen of Dr. Arthur Davies's case show that it differed in many [illegible]. [illegible] is to be observed that none [illegible] is fundamental. In all cases they are apparently to be explained on the ground that in Dr. Davies's case the disorder began at a much later age—that is, at a time when the formation of the body was completed. Hence the stature is not so short, the proportions are more adult, and the signs of premature senile decay are not so pronounced. But what is perhaps the most remarkable of these differences is that in Dr. Davies's case there is none of that emaciation which is such an outstanding feature of the earlier cases. This case bears out the opinion I have elsewhere expressed that progeria, like ateleiosis, should be divided into classes according to the age at which it begins. The cases hitherto recorded are examples of the progeria starting in infancy. Dr. Davies's case apparently began in late childhood. Doubtless it is sometimes also of fœtal origin, or does not show itself until adolescence, each class showing features distinctive of the period at which it began.

Progeria and Acromegaly.

There are a few points about progeria which demand comment, for they are peculiarly pertinent to what has already been said about ateleiosis. The infantilism of progeria is evidently of the sexual order, for in both the cases which I have described the primary sexual organs were not abnormally backward in development, and the epiphyseal ossification about corresponded with their ages. This latter point was confirmed by Professor Keith in his examination of the skeleton in this Museum. There are two deductions to be made from this. One is that it emphasises what has already been said of the relations of sexual development to infantilism, for it is evident that though in progeria there is no backward development of sex, yet the individual is, as Professor Keith shows, in many ways in a state of profound infantilism. Infantilism, therefore, is quite consistent with sexual perfection.

[28] THE LANCET, 1913, vol. i., p. 309.

The second point is that although morphologically these early cases of progeria are in so many important respects opposed to acromegaly they differ widely and fundamentally from Fröhlich's infantilism. Thus, so far from showing the lumpy obesity of pituitary infantilism, these beings are exceedingly emaciated. They resembled the extreme leanness to be seen in the victims of famine. And even more important is the fact that sexual hypoplasia, such an essential feature of pituitary infantilism, was certainly absent in all the male cases.

Finally, it is not possible to find any direct evidence of pituitary hypoplasia from an examination of the sella turcica. Professor Keith says of his case: "The pituitary fossa is smaller than normal, and yet the reduction in size is not sufficient to justify us in affirming that insufficient glandular tissue was present." And in Dr. Davies's case a skiagram of the base of the skull shows that the pituitary fossa is of normal size and appearance.

Hence the facts which bear on the relationship between acromegaly and progeria seem inconsistent, for whereas Professor Keith's osteological observations point emphatically to the one disease being the antithesis of the other, a comparison between the symptoms of pituitary overgrowth (acromegaly) and of pituitary undergrowth (Frohlich's infantilism) on the one hand, and of Fröhlich's infantilism and progeria on the other hand seems contradictory.

The view I have myself for a long time held in regard to these two conditions is that we ought to look upon progeria as in no way secondary to any derangement or imperfection of the pituitary body, but as itself primary and essential, the infantilism being in reality the fundamental condition and the senilism its immediate and direct outcome. Progeria is thus opposed to acromegaly only because progeria represents an extreme form of infantilism, whereas in acromegaly we see exaggerated features of senility. In this respect much the same may be said of ateleiosis. Indeed, Dr. Woods Hutchinson long ago pointed out the opposed characters of infantilism and of acromegaly. Infantilism is opposed to acromegaly because the infantilism perpetuates the childish or undeveloped type, no matter whether we regard it from the point of view of the individual or of the race; whereas acromegaly expresses in an exaggerated form the ape-like characters of senile decay as well as the degenerate, simian forms of evolutionary man.

CONCLUSION.

I am at the end of my subject, but cannot conclude without calling attention to its importance. It is of great importance, partly for its own sake, partly in its bearing upon the nature and relief of certain morbid states, chiefly for the sake of the strong light which it throws upon ordinary growth and development. The exaggeration of disease, like the lenses of a microscope, enable us by magnification to see features which would otherwise escape observation. No one can study such extremes as dwarfism, gigantism, infantilism, and senilism without coming to a far better understanding of normal growth and development than is possible to anyone who confines his investigation to the normal.

THE MORBID ANATOMY OF TUBERCULOSIS IN MAN.

By THEODORE SHENNAN, M.D. Edin., F.R.C S. Edin.,
PATHOLOGIST, ROYAL INFIRMARY, EDINBURGH; UNIVERSITY LECTURER ON MORBID ANATOMY, ETC.

(Concluded from p. 603.)

The Portals through which Tubercle Bacilli Invade the Human Body.—(Continued.)

The respiratory tract.—Under this heading there has already been considered the question of the portals of invasion in tuberculosis of the lungs and their regional glands, the conclusion being reached that most such cases arise from aerogenic infection. The next question to be dealt with is—

The relationship of tuberculosis of the tonsils and deep cervical glands to tuberculosis of the lungs and bronchial glands.—Orth was the first to demonstrate primary tonsillar tuberculosis. Aufrecht believed that the tonsils are the commonest portals of entry for the tubercle bacillus. Trautmann emphasises the importance of the tonsillar portal in tuberculosis of the cervical glands. Hansemann found primary tonsillar tuberculosis in only 1 per 1000 of his cases. Geipel and others regard tonsillar tuberculosis as invariably secondary to disease lower down in the respiratory tract.

On analysing the 111 cases of tuberculosis in children undergoing post-mortem examination in the Edinburgh Sick Children's Hospital during the period 1910–13—that is to say, during part of a period when special attention was being directed to the condition of the tonsils and cervical glands—I find that the tonsils were the seat of tuberculous disease in 11 cases (9·9 per cent.), and the cervical glands were caseous in 28 cases (25·2 per cent.). I have sought carefully for evidence supporting the view of Klebs and Grober that a tuberculous infection can pass directly from the lower deep cervical glands to the apex of the corresponding lung, and I can find only the following cases, and these can be explained on more rational grounds.

Case 1.—Male, aged 8 years. Extensive caseation of tonsils and cervical glands; fibro-caseous pleurisy over the whole of the left lung, and over the upper part of the right. Bronchial glands caseous, both sides. Subacute to chronic grey miliary, peribronchial tubercles Small caseous nodules in substance of spleen and kidneys. No ulceration of intestines. No excavation of lungs. Spread to peritoneum from pleura. Caseous nodules in meninges.

Case 2.—Male, aged 1 year. Right tonsil and cervical glands show advanced caseation; firm adhesions over the right apex; bronchial glands enlarged and caseous on the right side. Acute miliary tuberculosis of lungs, peritoneum liver, and spleen (the last also containing chronic tubercles). One small recent tuberculous ulcer in ileum.

Case 3.—Male, aged 13 years. Much enlarged and caseous supraclavicular glands on left side; mass of caseous glands at root of left lung, extending up to apex and pressing on it; numerous yellow tubercles in thickened pleura. Yellow tubercles in left lung; small cavity at *right* apex. Root and mediastinal glands enlarged and caseous.

In Case 1 we have a primary tuberculosis of the tonsils and cervical glands, lymph-hæmic invasion of the lungs, bronchial glands, spleen, kidneys, and meninges, and possibly a direct spread from the cervical glands to the pleuræ. The second and third cases may be explained in the same manner as the first, or as due to simultaneous infection through the tonsils and lower respiratory passages. I agree, therefore, with those authorities who maintain that no absolute proof of Klebs's and Grober's hypothesis exists, and that pulmonary tuberculosis seldom or never results by direct spread to the lungs from the supraclavicular glands, though it may do so by invasion from these glands, as from other parts of the body, by way of the lymph and blood streams.

Is an extension of tuberculosis possible from the cervical glands to the superior mediastinal and bronchial glands?—I have frequently noticed a continuous chain of enlarged and caseous glands stretching from the mastoid to the root of the lungs. Excluding those cases which an efficient examination shows to be the result of simultaneous ascending and descending infections meeting at the root of the neck, old lesions being present in the lungs and tonsils, I have no hesitation in asserting that, at least in Edinburgh, we occasionally meet with cases which one can explain only by assuming a downward extension throughout. These cases may be placed in two groups: (*a*) One in which extensive caseation and softening are seen in the clavicular group, or in the closely related group of glands in the superior mediastinum abutting on and sometimes infecting the thymus, the bronchial glands showing a more recent stage of tuberculosis, and the lungs showing either no tuberculosis or a more recent tuberculosis than that in the glands. (*b*) The other group of cases shows a continuous chain of caseous glands extending from the mastoid process to the root of the lung, the changes in the upper glands being of older date than those in the bronchial glands, the infection in the case of the lower glands being either retrograde or by direct extension *per contiguitatem.*

This I maintain, even in face of the acknowledged anatomical relationships of all these glands to the thoracic duct and angulus venosus, and also in face of the fact that in consequence one must assume a retrograde infection to the bronchial glands, just as in hilus phthisis one must assume a retrograde extension to the lungs from the bronchial glands, the channels through which have been blocked by caseation. Hart and Beitzke have shown conclusively that a retrograde infection of the lower tracheal glands can occur, partly as a result of the distension of the lymphatic trunks behind caseous glands, with resultant incompetence of their valves and stagnation of the lymph contained, and partly in consequence of the sucking backwards of the lymph towards the thorax, caused by the expansion of the thorax in inspiration. I may remark here that those authors who would restrict the progress of the tubercle bacillus to the ordinary anatomical lymphatic main channels apparently totally disregard the presence of anastomotic connexions between these channels.

A. P. Mitchell's work, in Edinburgh, is of great interest as showing the special danger run by the children in that city and neighbourhood from tuberculous infection by way of the tonsils and cervical glands. In 64 consecutive young children suffering from tuberculosis of the upper deep cervical glands he found histological evidences of tuberculous infection of the tonsils in 39 per cent. In 90 cases in which the cervical glands were clinically healthy the tonsils were histologically tuberculous in 6·5 per cent., and 10 per cent. gave positive results on inoculation of guinea-pigs. In a series of 72 consecutive cases of cervical gland tuberculosis, operated on by Mr. H. J. Stiles at the Sick Children's Hospital in Edinburgh, Mitchell found that 65, or 90 per cent., had been infected with the bovine bacillus, whereas only in 7, or 10 per cent., had the disease been caused by the human bacillus. The maximum incidence occurred during the second year of life. 84 per cent. of these children had been brought up upon unsterilised cow's milk. In not a single case amongst the 65 of bovine origin was there a history of pulmonary tuberculosis in other members of the family. Practically 50 per cent. of the cases came from rural districts in which there is little or no veterinary supervision of dairy cattle.

Lewis found that, of his cases of cervical tuberculous lymphadenitis, four-fifths of those over 15 years of age were due to infection by the human bacillus, whereas seven-ninths of those under 15 years of age were due to infection by the bovine bacillus. Carmichael and Stiles examined 50 tonsils from cases of cervical gland tuberculosis, and of these 7 (14 per cent.) showed histological evidence of tuberculosis.

Infection of thoracic glands from below.—The efferent trunks from the bronchial glands drain upwards, normally, into the angulus venosus, possibly having relationships with the efferents of the superior mediastinal and tracheal glands.

I have seen occasionally a large group of caseous glands situated behind the sterno-clavicular joint, and as frequently on the right side as on the left, involved in tuberculous caseation. These, I take it, correspond to the clavicular glands referred to by Beitzke, Hart, Most, and others. They also drain into the angulus venosus. This group may instead be the upper glands of the internal mammary chains which pass upwards behind the sternum on either side. Of these I can find no mention in the literature of tuberculosis. The efferents of these glands drain into the veins at the root of the neck, occasionally, as figured by Poirier, having junctions with the efferents from the bronchial glands. Their afferents come from the prepericardial glands, which lie along the anterior margin of the diaphragm, on its upper surface, and the afferents of these diaphragmatic glands come from the upper surface of the liver and from its hilic glands. I find tuberculosis of the prepericardial glands especially in extensive tuberculosis of the abdomen. These chains of glands afford a route for a spread of infection from the abdomen to the thoracic glands, and probably also to the pleura in addition to the recognised spread directly to pleura through the diaphragm. The following case is typical:—

Male, 17 months old. Ill for three months with diarrhœa and vomiting; fæcal fistula. Tonsils and deep cervical glands healthy, non-tuberculous. Isolated firm submaxillary gland on either side. General subacute adherent peritonitis; a few caseous mesenteric glands; retroperitoneal and hilic glands very large and caseous; semicircle of caseous glands above anterior margin of diaphragm; chain of internal mammary glands on either side of sternum, enlarged and caseous; large group of caseous glands behind the right sterno-clavicular joint Lungs and bronchial glands healthy, except for a few miliary grey tubercles. No tubercles in liver, kidneys, or spleen.

Other cases show, in the cervical region and thorax, only the group behind the sterno-clavicular joint tuberculous, with a varying amount of tuberculous change in the abdomen. It is well known that this group of glands frequently shows metastatic spread from carcinoma of the stomach, and the explanation advanced hitherto has been that the secondary invasion has taken place by retrograde transport from the thoracic duct. It seems extraordinary that the direct internal mammary route has been completely disregarded, particularly as its existence affords a much more satisfactory explanation. In exceptional cases I have found these superior mediastinal glands alone tuberculous, no disease being present in the organs or other lymphatic glands. Such cases are difficult of explanation.

Tuberculosis of the bronchial and root glands in relation to tuberculosis of the lungs.—Bartel regards the bronchial glands as especially susceptible to invasion by the tubercle bacillus. I have already referred to the view that this hyper-susceptibility is due to the circumstance that the bronchial glands are less trained in defence than the mesenteric glands, seeing that the latter, being associated with a hollow organ which is constantly full of bacteria, are constantly fighting against invasion by these bacteria, and are in consequence better trained to resistance.

Baumgarten and also Horton-Smith state that caseation of the bronchial glands is relatively infrequent in pulmonary phthisis, particularly in the adult. My own experience supports this statement. Köhler explains it on the ground that the lymphatic channels become obliterated by the chronic inflammatory processes going on to scar formation, which always accompany the more chronic forms of pulmonary tuberculosis.

Albrecht and Arnstein found either macroscopic or microscopic evidence of tuberculosis of the bronchial glands in 87 per cent. of cases between the ages of 6 and 16; and in 68 per cent. the disease was progressive. In relation to tuberculosis of abdominal glands, Rillet and Barthez found the relative proportion to be as 76 to 46; Guthrie, 54·5 to 26·6; Still, 81 to 59; Shennan, 65·4 to 53; Lapage and Mair, 55 to 71; Burkhardt, 58 to 30.

In 105 cases of tuberculosis undergoing post-mortem examination in the Royal Hospital for Sick Children, Edinburgh, between 1886 and 1889 the bronchial and mediastinal glands were found to be caseous in 82·8 per cent. In 308 tuberculous cases examined post mortem between 1889 and 1902 these glands were tuberculous in 62·9 per cent.; and in 111 cases dying from tuberculosis between 1910 and 1913 the same groups of glands were tuberculous in 54·9 per cent. The figures for these three periods thus show a progressive diminution, which accords with the general results given in Table I. Further, I may remark that this diminution, occurring along with a corresponding diminution in the death-rate from pulmonary phthisis, justifies my standpoint that both these manifestations of thoracic tuberculosis are in most cases sequels of an air-borne infection.

Taking the whole number of cases, the bronchial glands were caseous in 65·4 per cent. In a very high percentage of these cases there existed no older tuberculous change in the lungs, and I have formed the very decided opinion that in children in a very large proportion, possibly in the majority of cases, the spread of open tuberculosis of the lungs is rather from gland to lung than *vice versâ*.

There seems no reason to doubt that, as regards the original infection of the glands, the infective agent has reached them by way of the lungs, the tubercle bacilli being carried by phagocytes to the peribronchial lymphatics, along which they have then been carried to the bronchial glands, either with or without producing a primary tuberculosis of the lung or bronchus. One must also admit the possibility of a lymph-hæmic infection of the lungs and their regional glands, or of the glands alone by way of the lungs, from other parts of the body. The other routes by which an infective agent may reach the bronchial glands have already been considered.

Primary foci in the lungs.—We must now consider the question as to whether, in tuberculosis of the bronchial glands, an earlier lung focus exists in every case.

Goldschmid in his 595 cases found healed tuberculosis of the bronchial glands in 185 cases, against 272 cases in which there existed healed tuberculosis of the lungs without implication of the regional glands. In 5 per cent. of his cases there was isolated tuberculosis of the glands, and in 59 per cent. simultaneous tuberculosis of lungs and glands. Heinrich Albrecht and Anton Ghon are convinced that in every case an aerogenic infection is responsible for the primary lung focus which is always present, and is usually placed peripherally in the lungs. I have already referred to this view. Naegeli evidently regards all peripheral, slaty, scar-like areas in the lungs as of tuberculous nature and origin, whence his high percentage—almost 100 per cent.—of tuberculous infection in man. Burkhardt placed the figure at 91 per cent. Beitzke maintains that, unless caseous or calcareous alteration be present, it is a mistake to regard all these scars as of tuberculous nature, and lowers the percentage of tuberculous infection to 13·6, at ages 0 to 15 years, and to 58·2 per cent. in adults. Goerdeler also strongly supports this conclusion, and shows that disease processes other than tuberculosis can produce changes in the lungs extraordinarily like those of tuberculosis. Köhler maintains that by reason of the chronic inflammation always accompanying chronic lung tuberculosis the lymph vessels become obliterated, whence one may judge that he is of opinion that tuberculosis of the bronchial gland is not of necessity the sequel of the old lung infection denoted by these chronic foci; and I must say that I see no reason why they may not be due to a separate new infection in many cases. Preisich found tuberculosis of the bronchial glands in children of all ages, without demonstrable tuberculosis of the lungs. Hedrén regards the bronchial gland tuberculosis as invariably prior to the lung tuberculosis in the child; and Theodore Fisher looks upon measles and non-tuberculous broncho-pneumonia as acting like any other inflammation of the lungs by tending to facilitate a spread of tuberculous infection from the glands to the lungs.

Tuberculosis of the Lungs.

Very little really satisfactory has been determined in connexion with the localisation of tuberculous processes in the lungs.

Bacmeister and Rueben produced apical tuberculosis in rabbits by compressing the upper part of the lung and introducing small numbers of tubercle bacilli over a prolonged period of time. Orsós states that sub-pleural pigmentation is always greatest along lines corresponding to the intercostal spaces, and that in the same areas old scars of tuberculosis tend to be situated. Hence bacteria, like pigment, settle down in the lung where there is least movement and distortion of the vesicles. His conclusions may be correct, but his premisses are not quite accurate, to judge from my own experience, which agrees with that of Beitzke, Aschoff, and Marchand, and supports the view that pigment is first deposited along lines corresponding to the position of the ribs. This is most easily determined in cases of voluminous grey hepatisation in which the pleural surface of the lung is furrowed where it has been compressed by the ribs.

Benjamin Moore believes that the tubercle bacillus selects the least oxygenated parts of the lungs, and the observations of Serog support this view. He relates two cases in which compression of a main bronchus by an aneurysm had been followed by tuberculosis of the part of the lung served by that bronchus. Schmorl blames compression of the apical portion of the lung by the first rib, but Schmorl's furrow is not always present in apical tuberculosis. Hart and Freund believe that calcification of the first rib cartilage interferes with the function of the apical part of the lung and predisposes it to tuberculosis, but Schultze, Schiele, and Révész show that there is no evidence in favour of this, and maintain that the calcification of the first rib cartilage is rather a result of the firm adhesions which form over the apical portions of the lung. Certainly, judging from the almost invariable occurrence of this calcification after the mid-term of life in all cases undergoing post-mortem examination, and without in most cases involvement of the lungs, the relation of that condition to apical tuberculosis is, to say the least, doubtful.

We have to admit that the reason of the localisation of tuberculosis near the apices of the lobes is not yet clear, but it is probably in great measure related to some interference with the aerating function of these areas of the lung, and possibly partly to the tendency for particles conveyed in the respired air to settle down in the upper parts of the lung.

In children excavation may occur at any part of the lung, and almost as often in the basal areas as near the apices. It may be found at a very early age—for example, one of my cases was only 3 months old. Chronic tuberculous changes are not common in children, in whom the rule is to find rapid spread, with destructive changes and early generalisation. Nevertheless, evidences of resistance appear occasionally at an early age. Geipel found a tendency to localisation of tuberculous foci as early as the third month and calcification at the sixth month. I myself have found an old cavity at 5½ months, old, hard, caseous foci in the lung at the fourth month, chronic tuberculous pleurisy at the fifth month, and calcification of bronchial glands at the ninth month.

Hilus phthisis.—It seems to be quite certain that in some cases direct spread takes place from caseous root glands to the lung. Hilus phthisis is one of the results. Steffenhagen, Leon, Leslie, Jordan, and others, have discussed the question, and all pathologists have seen such cases. Geipel speaks of some cases of pulmonary tuberculosis as having the aspect of an aspiration infection. Erich Sluka with the aid of the X rays demonstrated its presence in 37 cases, and Jordan and Leslie confirm the usefulness of this means of diagnosis. It is apparently fairly satisfactory, but I must point out that Geckler found no tuberculous change at the post-mortem examination of a case in which hilus phthisis was diagnosed during life, with the help of the X rays.

Other Manifestations of Tuberculosis in Man.

I have dealt so fully with the manifold aspects of tuberculous infection of the thoracic organs that I have space for only a few remarks upon tuberculosis of the other organs and parts of the body. There is no room for doubt that in Edinburgh we meet with a larger number of primary alimentary infections than are found in most other parts of the world. Sims Woodhead, John Thomson, Fordyce, Fraser, Mitchell, McNeil, and I myself have published data proving this, so that I need not labour the point.

Intestinal tuberculosis.—In this connexion I have only one or two points to bring forward.

(*a*) When a recent tuberculous manifestation is found in the wall of the intestine, in association with older caseous tuberculosis of the mesenteric and retroperitoneal glands, one frequently concludes that the intestinal condition is secondary to the tabes mesenterica, retrograde infection having occurred. This conclusion is of questionable validity, the more plausible explanation being that the recent intestinal tuberculosis is really due to a new infection by organisms which have reached the bowel by deglutition, at a later period of time than those which have passed through its walls without causing a local lesion, but have been caught in the glands, and have produced caseation in that situation.

(*b*) In a case which I examined post mortem of cicatrising tuberculous ulceration near the commencement of the jejunum signs had been present during life of hypertrophic pyloric stenosis. The stomach was dilated and the pylorus was thickened; the duodenum was also dilated and its muscular coats were somewhat hypertrophied; but the ultimate cause of the symptoms and of these appearances in stomach and duodenum was as I have stated.

No new facts have emerged in connexion with *hyperplastic ileo-cæcal tuberculosis*, and I have nothing to add to what is already known about that manifestation of tuberculosis.

Fischer has made interesting observations on the channels along which invasion takes place from the alimentary tract. He shows that the blood route by way of the mesenteric veins is very seldom taken, but that invasion takes place as readily by way of the portal vein as by way of the lymphatics and thoracic duct. The liver acts as a bacterial filter (Weigert), but few of the bacilli caught in it produce serious lesions.

Meningeal tuberculosis.—It seems to be generally accepted that the usual channel through which the meninges are attacked is the blood stream. This is almost certainly correct, seeing that in the majority of cases an acute meningeal tuberculosis forms part of a generalised tuberculosis. But though it is not the usual route, as was taught by Greenfield, the lymph channel is not excluded. I have followed such cases during life and have found evidence post mortem that this route is sometimes taken.

Tuberculosis of bones and joints.—In a recent communication Stiles stated the case with regard to tuberculosis of bones and joints with admirable clearness. In tuberculosis of bones and joints infection practically always occurs by way of the blood stream; in a large proportion of cases the primary focus being situated in the lymphatic glands, especially the deep cervical, the bronchial, and the mesenteric. The localisation in the *bones* is determined by the distribution of the intra-osseal blood-vessels, and in children is most often in the growing end of the diaphysis (metaphysis), the end of the bone affected being determined by the direction of the nutrient artery. In the *joints* occasionally the synovial membrane *is primarily* attacked, for example, in the knee; but extension more often takes place from bone. The joints which possess small epiphyses—for example, the elbow and hip, in which therefore the diaphysis is near to the joint—are more readily and earlier attacked than others. In the rare cases in which the disease begins in the epiphysis it does so because these are large and begin to ossify at an early age.

In Scotland a large proportion of surgical tuberculosis is of bovine origin. The work of John Fraser is now well known. Of the 67 consecutive tuberculous bone and joint cases which he investigated the bovine bacillus was present in 41 (61 per cent.), the human bacillus in 23 (34 per cent.), while in 3 cases the bacilli were of intermediate type. In 41 of the children who were under 4 years of age 78 per cent. had been infected with the bovine bacillus. *In all of those under 12 months of age* the bovine bacillus was the cause of the disease, and every one of these had been entirely nourished on unsterilised cow's milk. For other interesting details one must refer to Fraser's paper. The important paper by Burkhardt is also well known. He investigated 29 cases of tuberculosis of bones and joints, and found the bovine bacillus in 3 cases only—ages 11, 14, and 19. Only 2 of his cases were under 3 years of age.

I regard the work of these two investigators as not necessarily contradictory, but instead they may be mutually complementary, seeing that the average age in Fraser's cases is 5½ years, whereas in Burkhardt's cases the average age is 15 years. I prefer, however, to regard their differing and apparently discordant results as affording one more proof of the prevalence of bovine infections in Scotland to a greater extent than is the case in other parts of the world, even in England—a fact that has been well recognised for some time by a few workers in Scotland. I therefore conclude that the relative frequency of bovine and human infections of bones and joints depends upon the relative frequency of bovine and human infections in general. Hence it is not surprising, but on the contrary, it is to be expected, that in those parts of the world in which human infections predominate greatly a larger proportion of cases of tuberculosis of bones and joints are due to infection with that bacillus than in parts—e.g., Scotland—where bovine infections are more frequent.

This argument suggests to me an interesting and very important point in connexion with *pulmonary tuberculosis* in children. If the conditions be as I have just stated, then the same reasoning should be applicable to tuberculous infections of the lungs and regional glands, and, provided it be the case that in children a lymph-hæmic invasion of the lungs can occur, then in pulmonary tuberculosis in children in Scotland we ought to have a larger proportion of bovine infections than elsewhere. It will be interesting to see if investigations just entered upon will show the validity of this argument. The great difficulty which will be encountered in such investigations is in connexion with the more chronic lesions in the lungs, because from previous work to which I have already referred the bovine tubercle bacillus, on long residence in the body, while retaining many of its characteristics, tends to lose its virulence, which after all furnishes one of the most important means for determining its identity. Nevertheless, it is hoped that in children this difficulty may prove less troublesome than is anticipated.

The Histogenesis of the Tubercle.

Joest and Emshoff found that the earliest changes in experimental animals is a proliferation of cells of connective tissue type, but most observers seem to agree with Baumgarten's original view that both connective tissue and endothelium are involved, and that the lymphocyte aggregation at the periphery of the tubercle is not essential, but is an indication of later chemotactic action. The method of formation of the giant-cell of tubercle is not yet settled. Most are in favour of its being due to a coalescence of endothelioid cells, but many still maintain that it is due to excessive proliferation of the nucleus of a single cell without the protoplasm participating in the cell division. Probably both methods are at work, though I believe that the former is the commoner.

Conclusions.

1. In Scotland the maximum death-rate from tuberculosis occurs during the 25–35 age-period; in England during the 35–45 period.

2. In Scotland the maximum percentage death-rate from tuberculosis calculated on the number of deaths from all causes, at each age-period, occurs in the female during the 15–20 age-period, and in the male during the 20–25 age-period. The percentage of deaths from tuberculosis in females during the 15–20 age-period is 52·69.

3. The death-rates from tuberculosis in different towns and cities in Scotland bear no clear relationship to the number of inhabitants or to the density of population. Other factors must be involved.

4. Hypersensitiveness due to a primary infection is probably of great importance in relation to reinfections. Reinfections arise not necessarily from a previous focus in the body, but must frequently be new infections from without.

5. The majority of cases of tuberculosis of the lungs and their regional glands are the result of aerogenic infection.

6. Retrograde infections do occur.

7. There is no evidence in favour of a spread by direct continuity from the deep cervical glands to the lungs.

8. The right lung and its regional glands are more often the seat of tuberculosis than the left.

9. In children manifest tuberculosis of the lung is very frequently a sequel of tuberculosis of the bronchial glands.

10. Little satisfactory is known of the factors which determine the localisation of the disease in the lung.

11. Chronic fibro-caseous tuberculous foci in the lungs and caseation of the related bronchial glands may be caused by separate infections.

12. In Scotland bovine infections in childhood are commoner than in most other parts of the world.

13. The relative frequency with which bovine or human infections occur in any given organ or tissue, and the differing incidence of these infections in different localities, depend on the relative general frequency of infections with these two types of the tubercle bacillus. This differs in different localities.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.—According to the fourth annual report of this association (1913) the chief feature of the year's work has been the encouragement given by the association to the establishment of schools for mothers. This has involved some curtailment of efforts in other directions, such as lectures and caravan tours. An entertainments committee has been formed to provide musical and dramatic entertainments at drawing-room "At Homes." Representatives of the association have been present at the conferences of several kindred organisations. The distribution of literature has been continued. The exhibit of model clothing for infants and children at the Children's Welfare Exhibition in January last excited so much interest that it has been sent on tour. Its purport is to show how money can be spent to the best advantage on clothes. The association now possesses three kinematograph machines, and has made several additions to its films. The Florence Nightingale Caravan made its summer tour through Kent in June, while the London Parks Caravan visited Tooting, Clapham, Streatham, Wandsworth, and Brockwell Commons, and Battersea Park. Considering the amount and variety of excellent social work done by the association it is regrettable to learn that there has been a considerable falling-off in the income of the association during the past 12 months.

THE SIGNIFICANCE OF DIABETIC FAMILY HISTORY IN LIFE ASSURANCE.[1]

BY OTTO MAY, M.D. CANTAB., M.R.C.P. LOND.,
MEDICAL OFFICER TO THE PRUDENTIAL ASSURANCE COMPANY.

IT is a commonly accepted belief that diabetes is in many cases a "family disease"—i.e., one which is prone to occur in several members of certain families in greater proportion than would be expected if its distribution were uniform throughout the population. If this be so, it becomes a question how far, if at all, one or more deaths from diabetes in a family history should influence our recommendation on the proposed life. From the actuarial point of view the proper method of investigation would be the comparison of the mortality table from a very large number of such proponents with that from an equal number of "controls"—cases chosen at random. Strictly speaking, the actuary is not concerned with the question of the family nature of the disease; his inquiry is whether such a family history increases the mortality from all causes—diabetes, consumption, senile decay, &c., and the investigation just suggested would afford him this information. The present paper, however, is a much less ambitious affair; it represents merely an attempt to see how far a family history of diabetes may be held to signify an increased risk of the proponent's death from the same cause. While this limitation will impair its value to the actuary, I trust that it will not render it unacceptable to the physician.

During the decade from Jan. 1st, 1901, to Dec. 31st, 1910, the total death claims in the "Ordinary Branch" of the Prudential Assurance Company numbered 76,333. Of these, the deaths from diabetes numbered 1143, or 1·49 per cent.[2] The family histories of these 1143 cases showed a death from diabetes in 41—i.e., 3·6 per cent. A control investigation of 1143 other cases, picked at random from the same period, showed a "positive" family history only in 12 cases—i.e., 1·05 per cent. These figures must be taken as the *minimal* rather than the actual ones. No case was included unless the word "diabetes" or "diabetic" figured in the history sheet. A fair number contained causes of death, such as "gangrene of the legs," "carbuncle," &c., of which a considerable proportion were probably diabetic. These were, however, excluded. On the other hand, it is extremely improbable that diabetes would be wrongfully given as a cause; almost alone among diseases, the ultimate confirmation of the diagnosis by a simple chemical test makes a positive statement exceptionally reliable.

The following figures for the parents of the two sets of 1143 cases are interesting as showing the vagueness of the histories:—

—	Parents living.	Parents died from some stated cause.	Parents dead, cause unknown, or senile decay.	Total.
Diabetic... ...	832	893	561	2286
Control	781	1066	439	2286

Among the 41 cases in which the history was "positive" there were two family histories of special interest, as follows:—

1. Two brothers (twins), aged 22 years, both unlicensed grocers, proposed for endowment assurance in October, 1901. Family history: Father, 64, healthy; mother, 63, healthy; two sisters living; one brother died from diabetes, aged 10 years. The proposals were accepted at tabular rates. Both brothers died from diabetes—one in January, 1909, aged 30; the other in September, 1910, aged 31.

2. Two brothers—one, aged 22, a carter, and the other, aged 17, a coachman—proposed for endowment assurance in 1902. Family history: Father, 52, healthy; mother, 48, healthy; three brothers living; seven sisters living; one brother died from diabetes, aged 11. The proposals were accepted at tabular rates. Both brothers died from diabetes—one in 1911, aged 26, and the other in 1912, aged 32.

Age at death.—Of the 1143 cases the family history, as mentioned above, was "positive" in 41, "negative" in 1102. Below I have arranged the ages at death of these two groups in decades for comparison and contrast:—

Years of age at death.	Diabetic family history.		No diabetic family history.	
	Number.	Per cent.	Number.	Per cent.
Under 20	—	—	3	0·26
21–30	8	19·5	74	6·71
31–40	14	34·1	155	14 07
41–50	5	12·2	196	17·80
51–60	5	12·2	333	30·25
61–70	7	17·1	251	22·80
71–80	2	4·9	84	7 61
81–90	—	—	6	0·50
Total	41	100	1102	100

Among the "positive" cases the percentage under 41 was 53·7, and among the "negative" cases it was 21.

The striking feature of this table is the large proportion (53·7 per cent.) of early deaths in the "positive" cases, in comparison with those (21 per cent.) in the "negative" ones. The probable explanation is that diabetes includes at least two different groups of cases: (1) A group in which the incidence is in middle or later life, the course comparatively mild, and the "family" factor absent; and (2) a group characterised by earlier incidence, more rapid termination, and a tendency to run in particular families. In the present series those with a negative history contain a preponderance of the former type, while those with a "positive" history include a large proportion of the latter type.

Influence of sex.—In the 41 cases with a "positive" history the affected member of the family and the average age of death of the corresponding proponents are shown in the annexed table:—

	Number of cases.		Average age of proponents at death.
Father diabetic	14	....	39 4
Brother ,, ...	13	....	38·5
Mother ,, ...	7	....	54 0
Sister ,, ...	7	....	50·0
Total	41	....	43·4

The striking feature here is the apparently great difference in the age at death according as the affected relative was male or female. Of the 41 "positive" case, 36 were male and 5 female, as follows:—

	Male.		Female.
Father diabetic	13	....	1
Brother ,, ...	11	....	2
Mother ,, ...	6	....	1
Sister ,, ...	6	....	1
Total	36	....	5

---

[1] Part of a paper read before the Life Assurance Medical Officers' Association on March 4th, 1914.

[2] The actual percentage is really higher, as 1143 represented the number of deaths from diabetes, while 76,333 was the number of policies, representing a smaller number of individuals.

Of the 36 males the average age at death was as follows:—

	Number of cases.	Average age at death.
Father or brother diabetic	24	38·3
Mother or sister ,, ...	12	49·3
Total	36	43·0

Of the 5 females the corresponding figures are:—

	Number of cases.	Average age at death.
Father or brother diabetic	3	43·6
Mother or sister ,, ...	2	68·0
Total	5	53·4

Without attempting to dogmatise on such comparatively slight data, one cannot help suspecting that the hereditary factor comes out more strongly in the male—that the death from diabetes of a father or brother is more ominous than that of a mother or sister, and that the male is more likely to suffer from "family" diabetes than the female. Unfortunately, the sex was not shown in every one of the 1143 cases investigated, so that one cannot say whether 36 to 5 represents an undue proportion of males among those with a diabetic family history. It is, however, interesting to see that, so far as they go, the Registrar-General's returns for 1911 bear out the relatively greater incidence of diabetes at younger ages in the male sex.

	Total deaths from diabetes.	Deaths at 40 or under.	Percentage.
Male	1936	462	23·8
Female	1917	400	20·8

The above analysis therefore suggests (1) that there is a form of "family diabetes" tending to occur at an earlier age, and proving fatal more rapidly than the ordinary "acquired" type of the disease; and (2) that this family diabetes is more likely to occur in the male than in the female.

I should like to take this opportunity of expressing my thanks to the Board of Directors of the Prudential Assurance Company for permitting me the use of the claims dealt with.

THE PATHOLOGICAL CHANGES OF THE THYROID IN DISEASE.*

BY RUPERT FARRANT, F.R.C.S. ENG.,
SURGICAL REGISTRAR TO WESTMINSTER HOSPITAL.

IN a publication on hyperthyroidism[1] it was shown, as was to be expected, that thyroid hyperplasia was not produced by thyroid feeding. In another paper[2] a hyperplasia was demonstrated in diseases such as infantile diarrhœa, measles, &c., and that it could be artificially induced in guinea-pigs by the injection of diphtheria toxin. Hale White[4] first pointed out if a large series of thyroids were examined they would be found to vary greatly. This was confirmed by Simpson,[5] who described thyroid changes in certain acute disease, and by Marine and Lenhart,[7] who examined a series of 73 from various conditions. No attempt has ever been made to separate the diseases according to their action on the thyroid.

The object of this paper is to point out those diseases and toxæmias that do, and those that do not, produce an alteration in the thyroid, to describe and demonstrate these changes, to compare them with those seen in goitre, and to note when they become associated with signs of thyroid excess. The work is based on some 700 thyroids obtained from post-mortem examinations during the last five years, together with some from guinea-pigs after inoculation. There is no wish to be dogmatic from the appearance of single sections, and doubtful ones have been as far as possible eliminated. It is proposed to take the micro-organisms in alphabetical order.

Bacilli.—B. aerogenes capsulatus: Nothing can be said with certainty from the thyroids obtained from 2 cases of spreading traumatic gangrene taken 36 hours and 4 days after infection. B. anthracis: The thyroids obtained from 5 guinea-pigs after inoculation showed a complete hyperplasia with intervesicular hæmorrhage. The change took place within 2 days. B. coli communis: 3 guinea-pigs received 2 intraperitoneal injections 16 days and 24 hours before death—total colloid absorption, marked cell hyperplasia, and intervesicular hæmorrhage were found. B. coliformis: Cultures of this organism, first described by McCarrison,[6] were obtained from a patient with endemic goitre. The organism merely decolourises sucrose-litmus and produces no indol. The induction of a coliform septicæmia produces total colloid absorption and cell hyperplasia. B. *diphtheriæ*: *The thyroids from 8 cases show stages of a complete hyperplasia and will be described in full later.* B. *dysenteriæ*: Emulsions of Shiga's and Flexner's organisms were injected into 6 guinea-pigs; an acute hyperplasia was produced. From 9 cases of asylum dysentery it was found that colloid absorption occurred after the fifth day, and that later a complete hyperplasia was produced. B. Gaertner: An active hyperplasia was found in 12 cases of infantile diarrhœa, the degree of which varied with the duration of the disease. B. mallei: 3 guinea-pigs were inoculated with glanders and a complete hyperplasia was found in 24 hours. B. tetani: 3 guinea-pigs were inoculated with tetanus and an acute hyperplasia was found; this in borne out by a thyroid from a child 12 days after an injury and 4 days after tetanic convulsions. B. tuberculosis: The thyroid changes have been gauged from 48 cases; the acute miliary causes a complete hyperplasia, the chronic a colloid hyperplasia. B. typhosus: Practically no change was found in 2 cases, 4 weeks and 9 weeks after infection.

Cocci.—Gonococcus: No change was found in 2 cases, one of which died from an injury, the other from lobar pneumonia. Meningococcus: A slight colloid hyperplasia was found in 2 cases that died on the twelfth and forty-second day respectively. Micrococcus catarrhalis: An acute hyperplasia was produced in 3 guinea-pigs by intraperitoneal injections. Micrococcus melitensis: The thyroids varied from a complete to a colloid hyperplasia in 12 Maltese goats whose serum reactions were positive. Pneumococcus: The thyroids from 39 cases of pneumonia varied according to the type and cause of infection. Lobar pneumonia *produces* no change, whilst broncho-pneumonia may cause a complete hyperplasia. Staphylococcus: In 8 cases of septicæmia due to pyogenes aureus or albus no thyroid reaction was present. Streptococcus: The thyroids from 41 cases of streptococcic septicæmia and other streptococcic *infections* show no change, *with the exception of those from cases of* scarlet and rheumatic fevers; the changes in these diseases may be due to other micro-organisms. Acute surgical infections are found to have no *effect* on the thyroid.

Protozoa.—Coccidiosis: No change was found in rabbits affected with coccidium. Spirochæta pallida: The thyroids from 19 cases of general paralysis of the insane and other late syphilitic affections show some intervesicular fibrosis. Malaria (blackwater fever): The thyroid from 1 case of five days' duration shows granulation and partial absorption of the colloid.

---

* A paper read before the Pathological Section of the Royal Society of Medicine on Feb. 17th, 1914.

Streptothrix.—Actinomycosis: Thyroids from two cases, one of eight and a half months' and one of four months' duration, show a colloid hyperplasia.

Diseases due to unknown organisms.—Measles: The thyroids from 8 cases show a complete hyperplasia. Acute anterior poliomyelitis: The thyroid from 1 case shows a mild chronic hyperplasia. Polyserositis: A thyroid from 1 case of polyserositis shows no change. Small-pox: Changes have been described by other observers. Whooping-cough: Extreme hyperplasia was found in 3.

Malignant disease.—The thyroids from 31 cases of sarcoma and carcinoma show no reaction except those in which death occurred from some complication capable of producing a thyroid change.

Gland diseases.—Addison's disease: The thyroids from cases of Addison's disease were found to vary according to the infection that produced the disease. In cases due to tuberculosis they vary with the extent of the tuberculosis situated elsewhere. The absence of suprarenal secretion appears to produce no thyroid change. Cirrhosis of the liver: The thyroids from 6 cases show cirrhosis of the thyroid with complete hyperplasia. Diabetes: In 3 cases no thyroid change was found. Jaundice: This disease produces no thyroid change. Diseases of the kidney: Renal disorders, either acute or chronic, are not necessarily associated with thyroid changes, though these may occur.

Blood diseases.—No thyroid change was found in a case of lymphadenoma, nor in a case of lymphatic leukæmia, but a colloid hyperplasia was found in pernicious anæmia.

Artificial toxæmias.—Injection of 0·0000025 grm. of ricin and 0·000025 grm. of abrin into six guinea-pigs causes an acute hyperplasia; a similar hyperplasia has been produced in some 50 guinea-pigs by injection of diphtheria toxin.

From these observations it is found that the thyroid changes are dependent on the amount, virulence, and duration of the toxæmia. The diseases and toxæmias may be divided into three groups; in the first are those that produce no effect on the thyroid, in the second those that produce a colloid hyperplasia, and in the third those that cause a complete or acute hyperplasia.

Group 1. Diseases that Produce no Effect.

Bacilli: Typhoid.

Cocci: Gonococcus (?), pneumococcus, staphylococcus aureus, staphylococcus albus, streptococcus equinus, streptococcus fæcalis, streptococcus puerperalis, streptococcus rheumaticus, acute surgical.

Protozoa: Coccidiosis.

Diseases due to unknown micro-organisms: Polyserositis, carcinoma, sarcoma.

Gland diseases: Addison's disease, diabetes, jaundice.

Blood diseases: Lymphadenoma, lymphatic leukæmia.

Group 2. Diseases that Induce a Chronic or Colloid Hyperplasia.

Bacilli: Coliform (chronic in man), tuberculosis (chronic)

Cocci: Micrococcus melitensis (goats), meningococcus (slight).

Protozoa: Syphilis (tertiary).

Streptothrix: Actinomycosis.

Diseases due to unknown micro-organisms: Acute anterior poliomyelitis, rheumatic fever, scarlet fever.

Gland diseases: Chronic nephritis.

Blood diseases: Pernicious anæmia.

Group 3. Diseases that Produce a Complete or Acute Hyperplasia.

Bacilli: Aerogenes capsulatus (?), anthrax, coliform (acute guinea-pigs), diphtheria (man), diphtheria toxin (horses, guinea-pigs), dysentery (asylum), dysentery (Flexner), dysentery (Shiga), Gaertner, mallei, tetanus, tuberculosis (acute).

Cocci: Micrococcus catarrhalis.

Protozoa: Syphilis (secondary), malaria.

Diseases due to unknown micro-organisms: Measles, broncho-pneumonia, small-pox, whooping-cough.

Gland diseases: Chronic nephritis, cirrhosis of liver.

Artificial toxæmias: Abrin, ricin, diphtheria toxin.

From tuberculosis one concludes that the toxæmias of Group 3, when mild in character, may produce a colloid instead of a complete hyperplasia; but no alteration in Group 1 can enable them to have the effect of either Group 2 or 3.

Diphtheria may be taken as an example of the acute toxæmias that act on the thyroid. The stages of the production of acute hyperplasia were illustrated by four thyroids taken from cases dead on the fourth, seventh, seventh, and twelfth days. The colloid becomes granular and then finally disappears, the walls of the vesicles become infolded, the outline indistinguishable, and the cells columnar in shape. The thyroids of the acute infections can be arranged in order; the degree of hyperplasia corresponds to the duration of the disease.

The involution of acute hyperplasia can be seen from specimens obtained after injection of sublethal doses of toxin or micro-organisms into guinea-pigs and of diphtheria toxin into horses. The vesicles are reformed by the direct transformation of the cells into colloid; they are small at first, but as fresh colloid is formed they enlarge and the cells become flattened; extravasated blood is transformed into fibrous tissue. At the termination of the process there is destruction of tissue with fibrosis. The fibrosis is the most marked feature after an acute hyperplasia, but excessive colloid formation after complete hyperplasia.

Production of colloid hyperplasia.—A complete thyroid circle can be traced over a period of years from cases of tuberculosis. Six thyroids were demonstrated on one slide and the contrast shown of the complete hyperplasia produced by miliary tuberculosis and of the colloid hyperplasia by the chronic. Three stages may be described in colloid hyperplasia. In the first the vesicles are small in size and the colloid coarsely granular with cell proliferation; in the second the vesicles are of unequal size and packed with colloid; the cell proliferation is squeezed up between them; finally the thyroid becomes cirrhotic with deficiency of thyroid tissue. Colloid hyperplasia is found in three separate conditions: during the involution after an acute toxæmia, during the production and the involution after chronic toxæmia.

Comparison with goitre.—There are two main differences between the hyperplasias of the toxæmias and those of goitre: one the hyperthyroidism of exophthalmic goitre when compared to the complete hyperplasias of the toxæmias; the other the alteration in size seen in endemic goitre as compared to that of the chronic toxæmias.

Repeated and double toxæmias.—Repeated injections of diphtheria toxin lead not only to the production of thyroid hyperplasia, but also to the formation of antitoxin. From observations on 15 horses it was found that the hyperplasia decreased as the antitoxic value of the serum increased. (A full account has already appeared in THE LANCET.[5]) This can be applied to the extent of saying that it is probable that the toxæmias that are counteracted by the formation of antitoxin only produce a thyroid hyperplasia when antitoxin is absent or deficient. Guinea-pigs were inoculated with a second toxæmia before recovery was complete from the first; it was found that there was an increase in the hæmorrhagic hyperplasia. The supervention of miliary tuberculosis on chronic is an instance of an acute toxæmia acting on a chronic; the extreme hyperplasia produced in such a case was shown; the case developed exophthalmos before death. Cirrhosis of the liver is an example of a subacute toxæmia that develops on a chronic at the onset of ascites; exophthalmos was present in 10 out of 12 cases. (A photograph of bilateral exophthalmos in a case of cirrhosis was shown, also the complete thyroid hyperplasia.) Barker[8] and Levison[9] have noted the occurrence of exophthalmos in cases of interstitial nephritis. These examples of the occurrence of exophthalmos are of importance in that they serve to bridge over the gap between the thyroid changes and hyperthyroidism of the toxæmias and those of goitre. These considerations enable one to trace the effect of the diseases on the thyroid from birth upwards, and lead to the prevention, production, and cure of certain thyroid conditions.

Queen Anne-street, W.

CASE OF ACUTE SUPPURATIVE APPENDICITIS COMPLICATED BY GANGRENE OF THE ILEUM.

BY BASIL HUGHES, F.R.C.S. ENG.

GANGRENE of the ileum complicating acute appendicitis is rare. This is the first case it has been my lot to encounter from a large number of acute inflammatory conditions of the appendix, and I cannot recollect or find any recorded cases other than that described by Dr. Joseph Wiener, of New York, in the *Annals of Surgery* for December, 1912. The following is my case.

The patient, a married woman aged 42, was suddenly seized with acute abdominal pain while taking a holiday in October last. She had never experienced a similar attack, and had up to the onset of the pain enjoyed good health. She went to bed, her bowels moved normally, and with fomentations and rest the pain, which was now localised to the right iliac fossa, subsided sufficiently to allow of her return home. She vomited at the onset and ascribed her condition to some food she had taken. On returning home, five days after the onset, she was seen by Mr. R. P. Woodroofe, of Eccleshill, who diagnosed a condition of acute appendicitis. Her temperature was then 101° F. and pulse-rate 94, her tongue was furred, and there was tenderness over McBurney's point, with some rigidity of the muscles covering the lower right quadrant of the anterior abdominal wall.

On the following day her temperature rose to 102°, the pulse-rate was 110, and in the afternoon I saw her in consultation with Mr. Woodroofe. There was now a definite tender swelling in the right iliac fossa; the rigidity was not very marked as the patient had had opium. The bowels were moving, the motions being very relaxed and containing mucus. There was tenderness on pressure in the right loin. The tongue was furred, and the patient looked sallow and toxic. A vaginal examination revealed some indefinite fulness high up in the right fornix. I advised immediate operation, but this was refused. Her condition became more grave, and I was called in to see her again 48 hours later. The pain and rigidity had now extended higher up on the right side, and the tenderness to pressure in the right loin was more pronounced. The pulse-rate had risen to 140 and was thready in quality. The tongue was dry and more furred. The abdomen was now distended, the tenderness was more general, and vomiting had commenced. The patient presented an abdominal facies and looked very ill.

Operation was consented to and was done forthwith. The tenderness in the loin suggested a retrocæcal position of the appendix, and under gas and ether anæsthesia the abdomen was opened through the right rectus muscle by an incision starting as high up as the umbilicus and extending downwards for about 4½ inches. A small quantity of seropurulent and inoffensive fluid escaped, and on further investigation the cæcum was quite fixed, very injected, and was bulging forwards very prominently, fluctuation being obtained across it. On the ileum about 4 inches from the ileocæcal junction there were two grey patches, one about the size of a large pea, the other slightly smaller. While examining these patches one of them gave way, gas and a small quantity of small intestinal contents escaping. This was rapidly mopped up, and both these patches were buried with Lembert sutures.

The small intestine was now packed off and the cæcum isolated. On its anterior surface was a gangrenous patch the size of a small pea. While investigating the cæcum a large retrocæcal abscess, containing very foul-smelling pus and gas, was opened. The appendix, which was gangrenous, was adherent to the posterior cæcal wall and was removed. Profiting by two somewhat similar cases of retrocæcal abscess I further explored this space and came upon a second abscess cavity which was extending around the right kidney. Being satisfied that this was the limit of spread of the pus, a large rubber drainage-tube was inserted high up through both abscess cavities; the second and smaller tube was inserted just down to the buried patches on the ileum. No lumbar drain was used. The gangrenous patch on the cæcum was buried with Lembert sutures, and the abdominal wall closed with through-and-through sutures of stout silkworm gut. The patient was given rectal salines and sips of water by mouth.

All went well for seven days, at which period the patient was taking milk, beef-jelly, and soups. After an enema on the seventh day some fæcal material was discharged from the tube draining the retrocæcal space. The other tube had been taken out. This small fæcal fistula persisted and was present when the patient went home five weeks after the operation, though most of the fæcal current was going the right way.

This case is of interest as it tends to support Dr. Wiener's theory that ileal gangrene in these cases is embolic. In my case the ileum did not enter into the formation of the abscess wall as it did in his; the abscess was entirely retrocæcal and the pus was pent up under considerable pressure. There was only a small quantity of inoffensive sero purulent fluid around the portion of the ileum that was gangrenous There was no further trouble with the small intestine after these two patches had been turned in. The buried patch on the cæcum evidently gave way, or perchance the cæcum perforated in another place.

This case, like two somewhat similar preceding cases of retrocæcal abscess, shows how undesirable it is to be content with stopping short after the pus is reached Retrocæcal abscesses have in my experience shown themselves to be often multilocular, and the failure to recognise this may explain how some of these cases progress to perinephritic and subdiaphragmatic abscess formation after what has apparently seemed a satisfactory operation In these three cases of retrocæcal abscess the patients had diarrhœa with the passage of mucus in the stools This may be that the cæcum itself is acutely inflamed through being adherent to a gangrenous appendix—in other words, a true condition of acute typhlitis existed

Paroxysmal Tachycardia in a Child —Secondary or Symptomatic Leukæmia

A MEETING of this section was held on Feb 24th, Dr PERCY KIDD, the President, being in the chair

Dr ROBERT HUTCHISON and Dr JOHN PARKINSON communicated a paper on a case of Paroxysmal Tachycardia in a child aged 2¾ years Dr Hutchison said that a case of this condition had not hitherto been described in so young a child When admitted into hospital he looked healthy, but the heart was rapid, the neck was pulsating, and a pulsating liver was felt The symptoms had been present for ten days There was nothing of significance in either the family or the personal history Two days later the child appeared quite normal and the liver had receded He knew of no other cardiac condition which could be accompanied by this sudden cessation of symptoms Three days later, after sitting up in bed, the patient suddenly developed another attack A similar clinical picture reappeared, the pulse rate being 245 per minute This attack lasted 20 hours and ceased as abruptly as the former During the next 10 days the child was perfectly well, the pulse rate being 64 to 80 per minute, and the tracings showing merely a sinus arrhythmia He was then discharged from hospital From this time (June 26th, 1913) until Sept 22nd, 1913, he remained well On that day a third attack began, which lasted for 12 hours, the pulse rate being 215 per minute A fourth attack occurred on Oct 3rd, the pulse rate on this occasion being 213 The child appeared cheerful and no abnormal signs were seen beyond the rapid pulsation in the neck and over the præcordia The liver was not enlarged This attack lasted 48 hours There had been no relapse since The Wassermann reaction was negative Dr Parkinson demonstrated the cardiograms which had been taken and which bore out the diagnosis —Dr G A SUTHERLAND said that the chief interest lay in what would happen to the child in later years He supposed that in this case, apart from the tachycardia, there was no other heart disease, and he thought it important that a distinction should be drawn between cases of paroxysmal tachycardia accompanying diseased conditions of the heart and those with a normal heart Before paroxysmal tachycardia had been investigated by recent methods it had been ascribed to excessive use of tobacco, alcohol, or tea factors which could not play any part in this case He showed three cardiograms of the condition, one of which was taken from a child aged 9 He considered that the auricle contracted while the ventricle was still in a state of contraction, this explaining the large venous wave demonstrable in the tracings, and also the large pulsating liver He had observed all the symptoms of cardiac failure result from a disturbance of rhythm, the musculature of the heart being apparently normal In that case, one of a child, he gave 45 minims of digitalis every day for 19 days, the heart slowed down and had acted well since His object had been to produce some degree of heart block and poisoning of the ventricle, so that the latter could not react to the unduly frequent auricular stimuli —Dr ALEXANDER MORISON did not think that they were in a position to say that the frequency originated in the auricle, for if so digitalis would influence it, as it did in auricular fibrillation, which Cushing had shown was not the case His own view was that it originated in the ventricle —The PRESIDENT recorded a case in a boy, aged 4½ years, who had suffered from attacks of blueness after contracting measles at the age of 2 They recurred about once a month and subsequently attacks of vomiting ensued In one of these a very rapid pulse had been noticed with enlargement of the heart and liver, and the condition had suddenly returned to normal In a later attack the pulse rate was 240 and the liver enlarged, but the child was perfectly happy and comfortable The pulse rate was not influenced by digitalis Vomiting occurred and caused a slowing of pulse At one time there had been a rapid pulse rate for six months without subjective symptoms He then became worse, with œdema, dyspnœa, and cyanosis and died suddenly Post mortem dilatation of the whole heart was found, with slight hypertrophy of the right ventricle and left auricle, but no valve lesion The case occurred before the advent of the new cardiographic methods and before the importance of the microscopical examination of the neuro muscular bundle and nodes was recognised

Dr G R WARD read a paper on Secondary or Symptomatic Leukæmia

SECTION OF DERMATOLOGY

Exhibition of Cases

A MEETING of this section was held on Feb 19th, Dr J H STOWERS, Vice President, being in the chair.

The following cases were exhibited —

Dr E G GRAHAM LITTLE 1 A case of Extensive Congenital Milium on the face neck, and body of a baby aged 4 months 2 A woman who presented large and small Patches of Atrophic Skin on the neck and shoulders, she had been seen by Sir Jonathan Hutchinson and by Dr J F Payne 15 years ago when the condition was designated "lardaceous disease of the skin" by the former and "papyrus skin' by the latter 3 A little girl with Favus of the Glabrous Skin of the Neck A perfect favus "cup" had been present and cultures showed the fungus to be the achorion quinckeanum There were no mice in the patient s house but two cats and seven canaries were kept, the father being a bird fancier The scalp was not affected —Dr J H SEQUEIRA, in reply to the CHAIRMAN, said he saw very few cases of favus now at the London Hospital —Dr J M H MACLEOD had had a case, diagnosed clinically as ringworm in which fungus was found in abundance in the feathers of a canary from which the infection was derived, and another recent case which showed extremely small pin s head sized scutula on glabrous skin

Mr J E R MACDONAGH A man with a "ringed eruption" on the penis occurring in the circumference of the scar of a sore which he had contracted 19 years previously Four weekly intravenous injections of salvarsan with intramuscular injections of mercury and iodide of potassium had been given, but had had little effect upon the lesions The Wassermann test had given a doubtful positive reaction The chronicity of the lesions, the limited localisation with no ascertainable symptoms of a generalised infection, the weak positive Wassermann's reaction and the failure of treatment to cure the lesions suggested to the exhibitor that the condition was an aberrant form of syphilis in which only the spores had been able to develop asexually —Dr A WHITFIELD asked if the tuberculin reaction had been tested or a guinea pig inoculated —Dr H C G SEMON and Mr HALDIN D DAVIS suggested that the "luetin reaction" might be tried.—Dr. A M H GRAY said the luetin reaction occurred in every case that had had syphilis, and it would not help in the present instance

Dr. H. G. ADAMSON demonstrated lantern slides of four cases of the Epithelioma Adenoides Cysticum of Brooke. There were seven cases in one family, four of which he had seen. In their clinical distribution and histological characters the growths resembled rodent ulcer. Brooke's cases had now been shown to be tricho-epitheliomata. The exhibitor regarded the tumours as embryonic hair follicles which were stimulated to growth at puberty and rodent ulcers as due to a similar process occurring later in life, and said a striking feature of these cases was that two of the patients developed large growths on the scalp which had been regarded as endotheliomata, but which microscopical examination showed to be tricho-epithelioma. Dr. A. EDDOWES and Dr. MACLEOD discussed the cases.—Dr. SEQUEIRA drew attention to the fact that Sir Frederic Eve was the first to propound the hair follicle origin of rodent ulcer, and pointed out that the latter was by no means a growth occurring only in old age, some cases beginning in the second decennium.

Dr. ADAMSON: A case of Adult Urticaria Pigmentosa in a woman, aged 44, of five years' duration, whose trunk and limbs were covered with freckle-like lesions associated with an urticarial element.—Dr. A. WHITFIELD thought the disease was one *sui generis;* he had observed a case in which a biopsy showed nothing characteristic.

Dr. W. T. FREEMAN exhibited an Extensive Bromide Eruption in a young child.

Dr. J. A. NIXON brought forward a case for diagnosis. The patient was a middle-aged woman who presented large discoloured patches on the back, with a cicatricial patch, resembling a cheloid, in the centre of the affected area; there was also a second patch of affected skin above the sacrum. He regarded the case as one of sclerodermia. The Wassermann reaction was negative and sections showed only fibrous tissue.—Dr. R. A. BOLAM suggested the possibility of an artefact, with which suggestion Dr. ADAMSON agreed.—Dr. E. STAINER regarded it as a typical case of sclerodermia, and the CHAIRMAN was also in favour of this diagnosis.—Dr. EDDOWES said that sclerodermia was never typical, and he had seen patches showing different characters in the same patient.—Dr. F. PARKES WEBER thought it most unlikely that this was a self-produced eruption.

Dr. NIXON: A case of Acanthosis Nigricans in a woman aged 39. She had noticed the appearance of warty growths all over her body last summer and more recently discolouration and thickening of the skin in the flexures. There was no evidence of visceral disease and all the functions were normal. Suprarenal, pituitary, and thyroid extract had been tried.—Dr. S. E. DORE asked if radiograms of the internal organs had been obtained, as he had observed a case in which skiagrams had revealed extensive malignant disease of the lung.

Dr. G. PERNET exhibited a woman, aged 56, suffering from an untreated rodent ulcer of the face of four years' duration.

Dr. G. NORMAN MEACHEN: A girl, aged 10, with an extensive Hairy Mole, chiefly affecting the "bathing-drawers" area, which was said to have begun at the age of 5. There were also three large lipomatous swellings situated upon the mole, and atrophy of the thigh muscles on the right side. There was a distinct history of maternal impression.—The CHAIRMAN had seen two cases of a similar character recently.

Dr. MACLEOD: A girl, aged 6, with Bald Patches on the Scalp, of two years' duration, following severe impetigo. The patches were dotted over with small papillomatous outgrowths. There was no history of favus or ringworm.—Dr. ADAMSON thought the large central and the small satellite patches strongly suggested a post-kerionic alopecia.—Dr. JAMES GALLOWAY thought the small papillomata on the bald areas were merely excesses of fibrous tissue.—Dr. MACLEOD, in reply, said the hair generally grew normally after kerion; and this was also Dr. SEQUEIRA'S experience.

Dr. MACLEOD: A case of Grouped Comedones in a girl, aged 2 years. The lesions consisted of grouped comedones, acne pustules, white fibrous scars, and minute fibrous thickenings on the back, shoulders, chest, and face, and were probably the result of camphorated oil and turpentine which had been rubbed on the skin by the mother for bronchitis. A comedo was examined for acne bacilli with negative results.

Mr. RUSSELL F. WILKINSON (introduced by Mr. MACDONAGH): A case of Dermatitis Herpetiformis of 13 months' duration; the whole body was covered with a generalised herpetiform eruption. The patient denied having had syphilis, but the Wassermann reaction was tested twice and was strongly positive on each occasion. Two injections of salvarsan had been given and had resulted in great improvement of the eruption. The blood count suggested a pseudo-leukæmic state.—Dr. SEMON had observed an identical case which had been under treatment for psoriasis for many years and subsequently developed dermatitis herpetiformis. There was no specific history. The blood count showed 27 per cent. of eosinophiles comparing with 22 per cent. in the present case.

Dr. KNOWSLEY SIBLEY: A woman, aged 42, suffering from Lupus Erythematosus affecting the face, mouth, and scalp. The lesions inside the mouth began at the same time as those on the scalp; the mucous membrane showed scarring and ulceration, and there was a peculiar sieve-like condition of the upper lip.—Dr. SEQUEIRA said that one of his clinical assistants had found lesions in the mouth in 28 per cent. of cases of lupus erythematosus.

Dr. C. DUDLEY CORBETT: A girl, aged 15, with Hypertrophic Lichen Planus on the right arm of five years' duration and linear in distribution; it had been much improved by one-third of a pastille dose of X rays.—Dr. MACLEOD said the patient was young for lichen planus, and thought the condition might be nævoid.

Dr. H. MACCORMAC: A case of Polycythæmia Rubra in a man aged 64. The condition began six years ago, and the rubicund condition of his face had since become more marked. The small blood-vessels could be very distinctly seen on the face and the skin was of a reddish-blue colour which was also well marked on the mucous membranes. Apart from a feeling of lassitude his general condition was fairly good.

Dr. SEQUEIRA brought forward a case of Multiple Idiopathic Pigmented Sarcoma which he had shown at the International Congress. The case was shown in order to illustrate the disappearance of the infiltrating growth which had taken place as the result of X ray treatment.

SECTIONS OF ELECTRO-THERAPEUTICS AND NEUROLOGY.

Use of Electrical Methods and the Value of Radiography in the Diagnosis and Treatment of Neurological Conditions.

A JOINT meeting of these sections was held on Feb. 20th, under the presidency of Mr. C. THURSTAN HOLLAND, when a discussion on the above subjects took place.

Dr. H. LEWIS JONES said the time had come for a review of the methods of using electricity, both for testing and for treatment, in cases of paralysis. In the treatment of paralysed muscles the current used must be a rhythmically varying one, with about 15 periods of action and of rest per minute. Also the current should be used for longer periods and of greater strengths than hitherto. Hence there was an advantage in using condenser discharges instead of induction coil currents, because they were more agreeable to the patient. Simple tetanisation of muscles tended rather to fatigue and to injure than to develop them. There were now several rhythmic interrupters on the market, two of which he demonstrated in action. With them the current grew from zero to maximum, and then faded again to zero; then followed an interval, and the cycle was repeated. The principles of ionic medication had taught one how to make large currents tolerable to the patient by a change in the form of the electrode. Treatments of infantile paralysis of half an hour's duration, repeated twice a day, were found practicable without any fatigue or exhaustion. The use of condenser discharges to take the place of the induction coil had been adopted by only a few observers; it was less painful than induction currents, and was more accurate for measurement. For six months he had used condenser discharges for muscle stimulation, to the exclusion of induction coils. The use of condensers for testing he had described in a previous paper. For treatment, discharges must be rapid enough to cause tetanic contractions in the muscles. This was ensured by employing a mechanically operated commutator, which charged the condenser from the source, and discharged it through the patient. In cases of nerve injury or nerve lesion ionic medication should be employed. He had seen very good results from it in facial paralysis.

Dr E P CUMBERBATCH read a contribution on Muscle Testing by the Condenser Discharge He pointed out that the character of the response to the galvanic current varied in the case of different muscles, and a cold muscle contracted more slowly than a warm one There was need of a method which would give a long range of stimulus, varying in duration from the shortest to which a muscle would contract, to the longest necessary to evoke response This was furnished by condensers of varying capacity, and their use caused very little pain The method, which he described in detail, enabled one to give an accurate prognosis in any given case, and he gave a number of instances

Mr W HAMPSON spoke of gratifying results he obtained at the Queen's Hospital for Children in cases of infantile paralysis from the method of rhythmical stimulation

Dr REGINALD MORTON spoke in support of the value of slowly varying currents, and reminded members of Dr Herschell's efforts of ten years ago, and his own device of a low periodicity three phase current which he used with advantage for intestinal conditions It had always appeared to him when using very large current densities for ionisation that a tetanic condition of tissues was being produced, which arrested the circulation to some extent and caused some spasm in the arterioles So he thought ionisation would be better if one could let the current be regulated by an interrupter

Dr E G FEARNSIDES and Mr S G SCOTT communicated a paper, profusely illustrated, on Diseases of the Pituitary Gland and their Effect on the Shape of the Sella Turcica

Dr N S FINZI emphasised the great importance in these cases of getting the rays through the fossa exactly lateral, and described his method of ensuring this

The subject was also discussed by Mr E S WORRALL and Dr F PARKES WEBER, and Dr FEARNSIDES and Mr SCOTT replied

LIVERPOOL MEDICAL INSTITUTION

Dislocation of the Shoulder —Lymphatic Leukæmia —Disease of the Pylorus

A MEETING of this society was held on Feb 19th, Dr E W HOPE the President being in the chair

Mr R E KELLY read a note on a Case of Fracture dislocation of the Shoulder The humerus was in three pieces; the head had become attached to the side of the shaft Mr Kelly freed it from the shaft and planted it in its proper position It became united and gave an excellent result —Dr N G CHAVASSE reported a case of fracture-dislocation successfully operated on by Mr Douglas Crawford —Mr T O LITTLER JONES related cases in which it had been necessary to remove the broken portion of the bone from the shoulder joint —Mr G P NEWBOLT referred to the value of pulling the arm right above the shoulder in the reduction of the dislocation —The PRESIDENT, Professor RUSHTON PARKER, and Mr F C LARKIN also joined in the discussion —Mr KELLY, in reply, discussed the regeneration of bone

Dr N PERCY MARSH gave a short paper on Three Cases of Lymphatic Leukæmia in Children The respective ages of the children were 11 4½, and 3 years The three children died within a few days or weeks of the onset of the symptoms In his experience he said, arsenic and blood serum were useless In concluding, he dealt with the etiology and pathology of the condition —Dr T R BRADSHAW related a case and upheld the view that the essential pathology was that of a neoplasm —Dr H R HURTER referred to a case of multiple myeloma which ended in a lymphatic leukæmia and suggested that such a sequence of events threw some light on the pathology of acute lymphatic leukæmia —Professor R J M BUCHANAN stated that the blood picture of a myelogenous leukæmia tended to show a change towards the lymphatic type as the disease became more acute or towards the end of the life of the patient He also pointed out that in a relapse subsequent to treatment by X rays the blood was more lymphatic in character

Mr NEWBOLT read a short paper on Some Cases of Disease Affecting the Pylorus and Necessitating Gastro-enterostomy He related a number of interesting cases illustrating the various points raised in the paper Among other matters discussed was the difficulty of diagnosing the nature of certain growths even when exposed by the surgeon, and the importance of having a pathological report at the time of the first operation He referred to the question of the value of pylorectomy, which in his opinion, when undertaken for malignant disease, was almost always disastrous He held a more favourable view of operations for palpable tumour of the stomach than was usual 10 or 15 years ago He also related a case in which the hernia of the small intestine had taken place in the lesser omentum —Mr LARKIN Professor RUSHTON PARKER, Mr K W MONSARRATT, Dr NATHAN RAW, and Mr LITTLER JONES discussed the paper —Mr NEWBOLT replied

Exhibition of Cases and Specimens —Dysentery due to Bacillus Y

A pathological meeting was held on Feb 26th Dr W B WARRINGTON, Vice President being in the chair

The following cases were shown —

Mr MONSARRAT (1) An Ulcer of the Pylorus which macroscopically appeared malignant but microscopically proved to be innocent, (2) two specimens of Ulcer of the Lesser Curvature of the Stomach, in one case caused by burns, (3) a Carcinoma of the Ileum, (4) a Nasal Polyp of large size, and (5) a Carcinoma of the Thyroid Gland

Mr NEWBOLT (1) A Small Hard Prostate, (2) a Carcinomatous Cyst of the Breast in a woman whose other breast had been removed 30 years previously for carcinoma, (3) a Malignant Sigmoid, and (4) a Mass of Axillary Glands removed with portions of the Axillary Artery and Vein

Professor ERNEST E GLYNN (1) A specimen of Acute Fibrous Pericarditis in a horse, and (2) (with Dr J H ABRAM) a Liver from a man aged 27, showing cirrhosis

Mr F A G JEANS and Mr C T HOLLAND Gall stones in a case with Stenosis of the Pylorus, and Urethral Calculi (240 in number) from a Pouch growing from the Urethra

Mr G C E SIMPSON Several Ureteral, Prostatic, Intestinal and Gall Stones

Professor BUCHANAN Specimens illustrating Leukæmia, and demonstrating the Life history of a Leucocyte —Mr. MONSARRAT discussed the formation of prostatic stones, and gave his opinion that they were formed in the gland itself —Dr STANSFIELD, Dr WARRINGTON, and Professor J M BEATTIE also discussed the specimens

Professor GLYNN read a note upon a case of Dysentery due to Bacillus Y which had been isolated by Dr J Bamforth from a patient in the Liverpool Royal Infirmary. —Professor BUCHANAN gave details of the clinical picture and of the treatment

Mr W P GOWLAND gave a demonstration of the Method of Reconstructing Embryos in Wax The special method of preparing the sections, the drawing of them by means of the Edinger projection apparatus, and the means by which the drawings were converted into wax plates, were explained with the aid of specimens and lantern slides. Models kindly lent by Professor Peter Thompson and Mr Rutherford were exhibited Dr Gowland pointed out the great necessity for cooperation in this branch of work between the practising physician and surgeon on the one hand and the pure scientist on the other hand —Dr WARRINGTON and Professor GLYNN discussed the paper, and Mr GOWLAND replied

EDINBURGH OBSTETRICAL SOCIETY.

Ethical Questions, Eugenic and Obstetric —Extra uterine Pregnancy

A MEETING of this society was held on Feb 11th, Sir J. HALLIDAY CROOM the President, being in the chair

Dr J HAIG FERGUSON read a short note on a case involving some Ethical Questions, Eugenic and Obstetric. The patient was an unmarri [illegible] parents, weak and facile, and [illegible] pregnant Her developmen [illegible] appearance by no means unattractive, but she undoubtedly would come under the class now recognised as ' degenerates ' Her pelvis was small the diagonal conjugate measuring not more than 3¼ possibly only 3, inches, which made the true conjugate about 2¼ inches, and the pelvis seemed uniformly contracted. When first seen she had passed the time for induction of premature labour with such a pelvis as hers, and the only possible treatment was Cæsarean section at or near full time. Eugenically it was probably advisable to sterilise this girl at the time of Cæsarean section, but this could not be done without her consent. From a medical point of view it was not usual to sterilise a woman nowadays in her first Cæsarean section, in the absence of other disease, however small her pelvis might be. The first child might not survive or might be weak or deformed, and it was right, now that Cæsarean sections were comparatively safe, to give the woman at least one more chance should she marry. Apart from the social difficulty in a case like this another question arose. If she were sterilised without her consent and later married, and it was discovered that she had been sterilised, no matter how good the reason might have seemed, a good claim for legal damages would probably lie against the operator. The parents of the girl, after full explanations, wished their daughter to be sterilised, and were willing to authorise it in writing, but it was doubtful if this would prove a legal safeguard in dealing with a girl of her age. The parents did not wish the girl or her neighbours to learn that she would be unable to conceive again. An unmarried woman's knowledge that she could not conceive might lead to disastrous results. The speaker knew of a girl who after removal of two ovarian dermoids became completely demoralised and ultimately syphilitic, though at one time of the highest character. In another recorded case a girl who had become syphilised vowed vengeance on the male sex and tried to infect as many men as possible. It might be said that medical men had nothing to do with the social or moral aspects on such a case as the present. On the other hand, nothing, however medically justifiable of itself, which was likely to bring difficulties into any community should be done.—Dr. D. BERRY HART considered the right thing was to do the Cæsarean section, leaving the girl as she was. An illegitimate child was very much neglected in this country and its fate was very hard, but abroad honorary guardians were appointed, and the father had to pay a certain amount. He knew cases where the illegitimate children of people in good society were allowed after the age of 14 to drift into the very lowest strata of society.—Dr. F. W. N. HAULTAIN had to operate on this patient during his term of duty. He thought her an intelligent girl. The parents had authorised him to sterilise her, but the patient absolutely refused to give any decision. He therefore had decided to operate and leave things as they were. If she lived it was conceivable that she might become worse in her habits and give rise to considerable disease, but also it was quite possible that if she had a child it might have a salutary effect on her.—Dr. J. LAMOND LACKIE said that two years previously at the Maternity Hospital a patient was admitted in the second stage of labour whose first labour (both were illegitimate pregnancies) required craniotomy. The conjugata vera was narrow; forceps failed and pubiotomy was mentioned to the patient, but she wished the child destroyed, as in the first labour. The child was alive. Craniotomy was done, but he wondered if one was justified in doing craniotomy (where the risk was as great as in pubiotomy) and thus destroying a possible useful citizen. Dr. Lackie felt that if pubiotomy was as safe as craniotomy he had done wrong.—Professor R. JARDINE (Glasgow) considered the proper thing had been done in the present case. In illegitimate cases he never sterilised the woman without some other good reason for doing so. If the woman married afterwards she ought to have the chance of maternity. In married cases he did sterilise with the patient's consent and many wished it. In cases requiring Cæsarean section he sterilised on a second operation. It might be asked, Why not let her go on? Recently he had had a case in which he had done Cæsarean section a third time. He had done the first, another doctor, who had refused to sterilise, the second. When the third operation was called for the union was so thin that it would have probably ruptured. Cases of rupture from this cause were admitted into the Maternity Hospital. The condition might be left till a second pregnancy, but if the patient or her husband refused consent it was not done. That was rarely the case though. He had done craniotomy when he thought it was best for the mother, but in similar circumstances to Dr. Lackie's he would be much inclined not to do it.—Dr. A. H. F. BARBOUR did not think one should do on a married woman what one would not do on an unmarried woman. If the woman subsequently married and her husband brought an action, he thought a judge would hold that the woman ought to have communicated that fact to her future husband. One must be careful about imposing laws and conditions on a patient as regards sterilisation from the point of view of moral degeneracy.—Dr. JAMES RITCHIE considered Dr. Haultain's action was the right thing to do. In Dr. Lackie's case he would have done the pubiotomy without consulting her; he did not think it was right to destroy a child because the mother wished it to be done.—Dr. LACKIE replied that one could not operate without consent.—Dr. JAMES YOUNG said statistics showed that in an aseptic woman the risk from craniotomy was practically *nil*, whereas that from pubiotomy, in which the conditions were similar, was at least 2 or 3 per cent., not to mention the risks to the locomotor powers of the patient. Dr. Lackie did the very best thing for the mother who, if the risks of pubiotomy had been known to her, would have refused. In a court of law the mother's interests were paramount.—The PRESIDENT said in the first case the question was, Was the woman really degenerate? If she was, with or without permission, one ought to sterilise. He agreed with Dr. Lackie's treatment of his case.—Dr. W. FORDYCE and Dr. H. S. DAVIDSON also discussed the paper.—Dr. FERGUSON, in replying, read a letter from Sir Thomas Clouston, in which he said that while it was difficult to conclude in the absence of a personal examination, the presumption was that the girl came under the definition of feeble-minded persons or moral imbeciles in the new Mental Deficiency and Lunacy (Scotland) Act, which he quoted. If that was so her parents' consent to operation would be a valid defence against action. But under the Act or not he thought a surgeon was fully justified in sterilising her as part of the Cæsarean section, as a preventive against the risk of another pregnancy in view of the possibility of natural delivery. With what would happen from an ethical or social standpoint the surgeon had practically nothing to do.

The PRESIDENT contributed a report on a case of Extra-uterine Pregnancy, which had developed to full term without giving rise to any symptoms whatever. The patient was sent in with supposed hydramnios. There was found to be a large quantity of fluid in the abdomen which was diagnosed as tuberculous peritonitis, and within it what appeared to be a pregnant uterus. Although thorough examination was difficult, there was no indication of anything but an ordinary pregnancy. After being eight years married this was her first pregnancy. She died suddenly, and on the abdomen being opened a large tumour, corresponding to a pregnant uterus at term, was found, and through a ragged opening in the left side posteriorly a fœtal foot projected. This was supposed to be a ruptured uterus. On further examination it was discovered to be evidently an eight months extra-uterine gestation sac containing a fœtus approaching term, and the uterus was enlarged 4½ inches and lay below the gestation sac. Apparently the original implantation of the ovum had been on the anterior and posterior aspect of the tube. The abdominal contents were matted together by a diffuse and extensive tuberculous peritonitis. The interesting point was that pregnancy had reached this stage of development without giving rise to any symptoms whatever; and the rupture also must have taken place practically without any symptoms.—Dr. W. FORDYCE, Dr. BARBOUR, Dr. FERGUSON, and Dr. HAULTAIN discussed the subject, and the PRESIDENT replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A meeting of this association was held at Storthes Hall Asylum, West Riding, at the invitation of Dr. T. Stewart Adair, and by the courtesy of the Visiting Committee, on Feb. 19th, under the presidency of Dr James Chambers.—A paper was read by Dr. H. Devine (Wakefield Asylum) on the Clinical Significance of Katatonic Symptoms. He said that katatonic symptoms are not necessarily significant of a deteriorating process, and the syndrome is frequently observed as a phase of the various forms of relapsing psychosis. The absence of confusion indicates a favourable prognosis, but a symptomatological diagnosis is not always possible. Especial attention must be paid to the make-up of the personality. Cases which deteriorate are usually found to have exhibited constitutional traits of an abnormal character before the outbreak of the psychosis. These habits are described under the heading of the shut-in personality. The cases which recover are dependent upon a hysterical or cyclothymic constitution, each with special reaction tendencies.—The paper was discussed by the President, Dr. Bedford Pierce, Dr. G. D. McRae, Dr. G. R. Jeffrey, Dr. J. G. Soutar, Dr. M. A. Collins, Dr. D. Bower, and Dr. R. H. Cole.—Mr. H. Salter Gettings (Wakefield) made a short communication on Bacteriological Investigations on Asylum Dysentery. He stated that the bacilli belonged to the group which did not touch lactose, and that he had found non-fermenting colonies in 44 out of 84 samples, and of these 44, in 39 the bacillus dysenteriæ was present. He had found that the bacillus was not always present in the same patient, and concluded this in some degree accounted for the high percentage of failures to isolate the organism.—Dr. W. H. Robinson and Mr. Gettings made a communication on the Pathology of General Paralysis. Four cases were quoted; in two the Wassermann reaction was negative, but the symptoms clinically and naked-eye post mortem were typical of general paralysis, but microscopically proved to be arterio-sclerotic in origin, and the spirochæta was not found in smears. In the other two cases the clinical and naked-eye symptoms were those of general paralysis of the insane, and the Wassermann was positive. These cases proved microscopically to be general paralysis of the insane, and the spirochæta was isolated in both cases. Mr. Gettings thought that clinical general paralysis of the insane might be of two origins, and this might explain the controversy between the "no syphilis, no G.P." school and others.—Dr. Devine, Mr. T. Graeme Dickson, and Dr. Soutar discussed the paper.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 13th, Professor T. Wardrop Griffith, the President, being in the chair.—Pro[illegible] of Fragilita[illegible] that gave [illegible] by lantern slides.—The paper was discussed by Mr. W. Thompson, Mr. S. W. Daw, Mr. F. H. Mayo, Mr. H. Collinson, and Mr. J. F. Dobson.—Dr. W. H. Maxwell Telling and Mr. Daw showed a case of Rheumatoid Arthritis. The patient, who had been unable to walk for the past five years, had had the knees straightened forcibly after tenotomies, and could now walk in caliper walking splints.—Mr. Collinson showed a Ureteral Calculus which had been passed spontaneously. The calculus could be felt by a ureteral catheter which was passed beyond it. Olive oil was injected into the ureter above the calculus.—Mr. Alexander Sharp showed a patient with a Dental Cyst invading the antrum of Highmore. A skiagram showed the cyst involving the larger part of the antrum. It was proposed to treat the case after the radical method of dealing with chronic antral empyema.—Mr. Dobson showed specimens from cases illustrating the association of acute appendicitis with tuberculosis of the ileo-colic glands.—Mr. Mayo showed bone specimens from a case of Osteomalacia with skiagrams.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 18th, Mr. R. G. Hogarth, the President, being in the chair.—Dr. J. S Risien Russell, physician to the University College Hospital, gave an address on the Affections of the Nervous System which are responsible for Ataxia. After having enumerated the various affections which caused ataxia the lecturer in great detail dwelt on the differential diagnosis of tabes, disseminated sclerosis, subacute combined degeneration of the cord, peripheral neuritis, cerebellar tumour, and Friedreich's ataxia. The lecture was illustrated by lantern slides.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual general meeting of the governors will be held at the hospital on Thursday next, March 12th, at 5.30 P.M., Sir Stuart M. Samuel, Bart., M.P., a vice-president of the hospital, in the chair, to receive the annual report, and elect the committee of management, the treasurer, and auditors for the ensuing year. All governors, including ladies, are invited to attend.

Reviews and Notices of Books.

A Manual of Operative Surgery with Surgical Anatomy and Surface Markings.

By DUNCAN C. L. FITZWILLIAMS, M.D., Ch M. Edin., F.R.C.S. Eng., F.R.C.S. Edin., Surgeon in charge of Outpatients, St. Mary's Hospital; Senior Assistant Surgeon to [illegible] Cox. 1913. Pp. 450. Price 10*s*. 6*d*. net.

THIS text-book, so the author tells us, is intended, not for the operating surgeon, but for two classes of readers who have not trodden so far on the road of surgery: in the first place for the student, who needs to learn even the most elementary groundwork of the subject, but to whom the practical details are of comparatively little importance; and also for those whom the author describes as the journeymen craftsmen of our profession, who are able to value the practical importance of details in the mode of carrying out operative procedures. Mr. Fitzwilliams has, wisely we think, incorporated in his book an ample account of the surgical anatomy and surface markings which are of so much practical importance in the operations of surgery, and yet are often omitted in works relating thereto.

From a careful examination of this work we feel fully satisfied that the author has achieved his aim in providing for his readers a good and trustworthy treatise on the methods of operative surgery. There is a tendency at the present time among some surgeons to disparage the form of teaching operative surgery which has prevailed for many years; for, in their opinion, the student is taught many operations which he will never perform or see performed in practice. Instead of a set amputation he will see a surgeon amputate a limb where the injury has necessitated the operation, and the flaps will be cut according to the amount of skin which is left. All this is very true, but there are no sufficient reasons for banishing from our text-books the methods which are ideal, and yet which are seldom if ever applicable to cases as they occur in practice. In the study of mathematics the student has to solve many problems which will never occur in practice. It is said that it is useless for the student of surgery to tie blood-vessels in their continuity, for in practice these operations are hardly ever done; but here again the student's skill is trained, and even the practical knowledge so acquired will be of great benefit to him hereafter. It is true that to the operations of the past many new ones have been added, and these should always be included in a course on operative surgery for students, and this has been done in this case; but we should regard it as a distinct mistake to exclude the old ones. All operations are of value in the training of the student, and a very large number of operations is possible on one cadaver.

We have not seen any work which is better suited for the student or the young practitioner than this, and the illustrations are numerous and adequate. We must acknowledge that we are pleased to find that the author has employed the usual nomenclature in the use of anatomical terms, instead of the inaccurate and eccentric names of the Basle nomenclature. He will doubtless agree that reform of our anatomical names is needed, but it must be a reform founded on common sense.

of these deal with the "Bausteine," or the amino-acids and their conjugations, to produce peptones and polypeptones. A very full account is given of the distribution, constitution, functions, and mode of formation of the proteins both in plants and in animals. The results of their digestion in the alimentary canal are fully set forth, and the fate or destiny of the products of their intestinal proteolysis is followed throughout the body. To the actions of the intestinal flora and the amino-acids of the intestine one lecture is allocated; another to what happens to the amino bodies after they enter the blood from the intestinal canal. Their relations to cell metabolism are intimately discussed and the final products of protein metabolism are then considered. Two lectures suffice for the nucleo-proteins and nucleic acid. Blood and its colouring matter, chlorophyll and other colouring matters occupy one lecture, while the last lecture deals with the origin of blood and its pigment, their condition in the animal organism, and the relation of hæmatin to the bile pigments and urobilin. The story of the bile salts brings the lectures to a close.

This is a most commendable and elaborate presentation of a subject which is growing daily in importance, and one which must command more and more the attention of teachers of physiology and biochemistry to medical students. Part II., which deals with the Inorganic Nutrient Bodies, is announced to appear in the spring of this year.

School Clinics at Home and Abroad.

By LEWIS D. CRUICKSHANK, M.D. Aberd., D.P.H. Cantab. London: The National League for Physical Education and Improvement. 1913. Pp. 171. Price 2*s.* 6*d.* net.

THIS book is divided into three parts, of which the first deals with the problem of treatment, and, describing the available means, enters into a general description of the school clinic; Part 2 deals with clinics actually in operation at home, and Part 3 with clinics abroad. So rapidly does the school clinic movement progress that the second section is not now full enough, but this does not impair the value of the work as a book of reference for the school medical officer and the educationist.

Dr. W. Leslie Mackenzie, in the introduction, states that "the present volume has been prepared for the active citizen," and the book will serve the "active citizen" interested in education very well; but it would have served him even better had the style of the writing been clearer and more crisp. The legal aspects of the problem of treatment occupy the second chapter. The available means of treatment are dealt with in the third, and the arguments for and against treatment at hospitals are fairly set out, as is also the "attitude of the hospitals," an attitude usually antagonistic to the undertaking of treatment for school children's ailments. From the standpoint of the school medical officer Chapter VI., on The School Clinic: its Departments and Work, is of particular interest, illustrating as it does, from the case of existing institutions, what can be accomplished. The photographs appended will help to convey a vivid idea to the lay mind of the work that is being done by school-clinics. The departments into which a clinic's treatment work can be divided are given as: A. General medical department: (1) treatment of minor ailments, (2) cleansing schemes, and (3) X ray treatment of ringworm. B. Ophthalmic department. C. Dental department. D. Orthopædic department. E. Operative department. Any one of these departments may be started separately and others added as need and opportunity arise. The staff and accommodation needed for a clinic and the cost are all separately considered with reference to schemes in operation.

This is a useful volume and should do much to explain the reasons for the institution of school clinics to a public that is too ready to regard them with prejudice.

Handbook of Diseases of the Rectum.

By LOUIS J. HIRSCHMANN, M.D., Lecturer on Rectal Surgery and Clinical Professor of Proctology, Detroit College of Medicine. Second edition. Illustrated. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1913. Pp. 339. Price 18*s.* net.

WE reviewed the first edition of this work on its appearance, and we are pleased to welcome a second edition. It retains all the good points which rendered the earlier issue a very convenient text-book for the general practitioner who wants to know something more of the surgery of the rectum than is contained in the surgical text-books, and, in addition, this issue has several new features which enhance its value. Especially we would mention the account of the use of quinine and urea hydrochloride as a local anæsthetic; this substance is not employed to the extent which it deserves, for it is very safe and its action is long lasting. The technique of operations on the rectum with the aid of local anæsthesia has been very fully described, and this should prove of value.

We can cordially recommend the book as a very practical introduction to the diseases of the rectum.

LIBRARY TABLE.

Collected Reports of the Department of Neurology, Harvard Medical School. Volume V. 1912.—The fifth volume of reprints of contributions emanating from the neurological department of the Harvard Medical School contains several from the pen of the veteran neurologist, Dr. James J. Putnam. Among these may be enumerated Personal Impressions of Sigmund Freud and his Work, Personal Experience with Freud's Psychoanalytic Method, on the Etiology and Treatment of the Psychoneuroses, a Plea for the Study of Philosophic Methods in Preparation for Psychoanalytic Work, on Freud's Psychoanalytic Method and its Evolution, and Comments on Sex Issues from the Freudian Standpoint. It will be seen, therefore, that Freudism has entered largely into the work in recent years of the Boston neurologist. There are also papers by Dr. E. W. Taylor and Dr. G. A. Waterman bearing more or less on the Freudian hypothesis. Of the 18 contributions in this volume of reprints only four are concerned with organic nervous disease. The general level of the papers is high, and the reputation of the department has been worthily maintained.

Explanatory Lectures for Nurses and their Teachers. By H. HAWKINS-DEMPSTER. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1913. Pp. 224. Price 3*s.* 6*d.* net.—This book will, we think, be found very useful by those for whom it is intended. It is, in fact, a commentary on the ordinary course of lectures on nursing, elucidating various points. The work is divided into 13 "subjects" which are treated respectively in one, or more generally two, "lectures." Thus, Subject I.

deals with the keeping of charts, Subject VII. with bacteriology, Subject X. with dropsy, and Subject XIII. with observation and precision. The book is written in a simple yet interesting style, and one good though somewhat unusual feature is the use made of analogies and comparisons between pathological or physiological processes and everyday occurrences—e.g., "We may roughly compare the heart and the circulation to two covered platforms built back to back within one station, with double lines in common, but with no passage through the station itself." Mr. Hawkins-Dempster then explains that passengers start from platform A, journey by the outgoing lines to market towns (the capillaries), where they buy and sell, and return, exhausted and soiled, by the ingoing lines (the veins) to platform B (the right side of the heart). Further on he explains the pulmonary circulation in similar fashion. Again, the condition of the blood-vessels in sclerosis is well compared to the lesions seen in old water-pipes, where the glaze has given way or has been worn off, so that the unprotected earthenware has disintegrated, or deposits of lime or chalk have been formed, and the calibre of the pipe is seriously lessened. Besides the 13 subjects, there are four supplementary lectures, intended not for trained or training nurses, but for "first aid" hearers, which deal with fractures and hæmorrhage. The book is eminently practical, and many a medical man who has to lecture to nurses will find it useful; not that it will teach him any new medical or scientific fact, but it will give him "tips" for imparting knowledge, a faculty which is by no means common to those possessing it.

A Manual of Ambulance. By J. SCOTT RIDDELL, M.V.O., M.B., C.M. Aberd., Senior Surgeon and Lecturer on Clinical Surgery, Aberdeen Royal Infirmary. Sixth edition. Illustrated. London: Charles Griffin and Co., Limited. 1914. Pp. 254. Price 6*s.* net.—This work was first issued in 1894, and during the 20 years that have elapsed it has passed through six editions, with considerable enlargement. In the present volume sections on artificial respiration, the treatment of electrical accidents, and on ambulance transport have been added. The information given is complete and clearly arranged, and is illustrated by more than 200 figures, many being full-page plates. The chapter on Voluntary Aid Detachments and their Work is excellent; as a concrete instance of practical organisation the author takes the case of the Highland Division and Mounted Brigade of the Territorial Force, called out to oppose a landing on the shores of the Moray Firth. A specially prepared map is inserted, showing the disposition of medical aid detachments. Such a well thought out scheme is exactly what should be prepared *mutatis mutandis* by all auxiliary detachments throughout the country. Another valuable chapter is that on the first-aid treatment for accidents from electricity. In applying the "reversed bandage" (page 41), for "thumb of right hand" should be read "thumb of disengaged hand" (as it varies with the limb bandaged). No more comprehensive or better illustrated manual of ambulance work could be wished for than Dr. Riddell's volume.

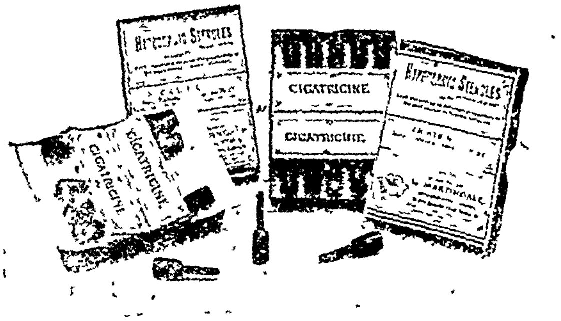
JOURNALS AND MAGAZINES.

Parasitology. Edited by GEORGE H. F. NUTTALL, F.R.S., and ARTHUR E. SHIPLEY, F.R.S., assisted by EDWARD HINDLE, Ph D. Volume VI., No. 4. January, 1914. Cambridge University Press. Price 10*s.* net; yearly subscription £1 10*s.*—The Trematode Parasites of North Queensland, I., by William Nicoll, contains the descriptions of 12 new species, two of which represent new generic types. This paper is the first of a series on the trematodes of Queensland and the Northern Territory, and is of special interest considering the economic importance of parasitic worms.—Pseudo-Parasitism, by A. E. Shipley, is a record of two very curious cases of pseudo-parasitism which have come under the author's notice. The first case is that of a woman, aged 68 years, from whom centipedes had been vomited and passed during a period of 12 or 18 months. Some of the centipedes emerged through the patient's nose, and as many as seven or eight, sometimes more, were daily leaving the alimentary canal. According to the statement of her medical attendant some hundreds of these animals had left the body. Their presence produced vomiting and some hæmatemesis, and treatment with thymol, malefern, and turpentine had no effect in removing the creatures. The specimens were identified as belonging to the species *Geophilus gorizensis* Latzel, and considering the breeding habits of this centipede it is almost impossible to conceive that the animals are capable of multiplying in the intestine. In the second case the author had sent a partially digested specimen of a slug, Milax marginatus (Müll.), which had passed through the alimentary canal of a doctor.—Regeneration in Argas persicus, by Edward Hindle and Norman Cunliffe, is a somewhat technical paper, concerned, as the title implies, with the study of regeneration in the fowl tick. With the exception of the adults all stages of the tick possess very considerable powers of regeneration. In addition, from their experiments the authors are of the opinion that in Argas persicus there is a tendency towards the suppression of the free larval stage, as in the case of Ornithodorus moubata, the human tick.—Rhipicephalus sanguineus: Variation in Size and Structure due to Nutrition, by Norman Cunliffe, is a decided confirmation of Nuttall's previous work on this subject, in which he expressed the opinion that the variation in size of ticks is mainly due to their being forcibly removed at various stages of engorgement. The striking effects of malnutrition in the case of R. sanguineus are well shown in the present paper.—Observations on Argas brumpti, Neumann, 1907, by Norman Cunliffe, contains nc [illegible]
description of the k [illegible]
tick.—The Anatomy [illegible]
by L. E Robinson an [illegible]
these authors' monograph of the anatomy of the common fowl tick. Nothing seems to have been left untouched, and now that the full monograph has appeared, with its magnificent coloured plates and wealth of illustrations, the authors are to be congratulated on the completion of a work which will remain as a basis for all future study of that most important group of parasites, the Ixodoidea.

The Philippine Journal of Tropical Medicine, Vol. VIII., Section B, No. 5.—The first article in this number is on Experimental Balantidiasis, by Dr. E. Linwood Walker, and is illustrated by 7 plates. Dr. Walker states that the affection caused by balantidium coli is relatively common in man in the Philippine Islands, and a large proportion of pigs are similarly affected, balantidia being passed in the resistant encysted stage in the stools of the infected animals, which are to be regarded as the chief source of the human disease in that part of the world.—Dr. R. B. Gibson gives the results of a number of experiments he made on the Influence of Compensated Salt Mixtures on the Development of Polyneuritis Gallinarum and Beri-beri. He concludes that the addition of such a mixture to white rice, with which fowls are fed, does not prevent the development of polyneuritis, though the onset of the disease is slightly delayed and the degenerative changes in the nerves are less pronounced. This paper is illustrated by 4 plates.—Dr. A. Marshall Barber gives an account of an unusual disease which prevailed in epidemic form at Buki, Ambos Camarines, on the island of Luzon. It was characterised by an inflamed spot or nodule on the skin, with severe constitutional symptoms, and was often fatal. Plague and anthrax were excluded, the only positive laboratory findings being pyogenic cocci. No similar epidemic had been previously observed.—The same author contributes another paper, illustrated, in continuation of previous investigations on the same subject, on the Infection of Achyla, one of the fish moulds, with various micro-organisms.—Dr. W. E. Musgrave and Dr. A. S. Sison describe four cases of Acute Malignant Glanders in Man, and Dr. C. M. Reyes furnishes a short article on Noma in the Philippine Islands, with report of a case

"STERULES"

(Reg. Trade Mark.)



THE IDEAL FORM OF HYPODERMIC MEDICATION.

A Surgeon in Cape Colony wrote shortly after the Boer War:

> "I am much taken with the Hypodermic Sterulès. During the war I always felt the uselessness of the hypodermic tablet (owing to the absence of clean water). I fancy that if I had had Sterules and a small bottle of Antiseptic Solution (for the skin and syringe) I would have used morphia in first aid on many occasions.
>
> I am, yours truly, M.R.C.S., L.R.C.P. Lond, D.P.H. Camb."

	Box of 10. (Prof.)
Adrenalin Solution 10 m., with elongated ends (8 in box), 3/-; 15 m.	4/-
A convenience in dental work, &c. (The 15 m. size is used in conjunction with B. Eucaine Powders in Infiltration Anæsthesia.)	
Adrovaine (Adrenalin 1/250 gr. c. Stovaine, 1/3 gr.	4/-
Adreucaine, ½ Cc.	2/-
Containing Adrenalin 1/4000 gr. and Eucaine 1/12 gr. in 8 m. (½ Cc.) for dental and surgical use.	
Æther, ½ dr.	3/6
Antipyrin, 4 gr. (and with c. Cocaine, 1/20 gr.)	2/6
Apomorph. HCl., 1/10 gr.	3/6
Arrhenal, 2/5 gr., also 3/5 and 3/10 gr.	2/6
"**Arsamin**," ½ and ¾ gr. in 17 m. (Non-toxic Org. Arsenic)	2/6
Arsenic and Iron, No. 1 (weak) or No. 2 (strong). (Most successful in Anæmia)	3/-
Atrophine, 1/100, and Strychnine, 1/60 gr. each. (For use with Scopolamine Morphine Injection)	2/6
Atropine, 1/60, with Strychnine, 1/30 gr. Also 1/50 with 1/30 gr.	2/6
Cacodylatum Co. Inj. 17 m.	4/6
Caffeine Sod. Benz. 1 gr.	4/6

LONDON: SATURDAY, MARCH 7, 1914.

Vested Interest in Public Appointments.

THE interest that a lawyer or a firm of solicitors, a medical man or a firm of medical practitioners, may have in a public appointment is not easy to define, and therefore the filling up of any vacancies as they occur is not infrequently the origin of trouble. A lawyer has been, for example, under-sheriff or clerk to the justices with complete satisfaction to the public and to those whom he especially serves; what right has he to expect that on his retirement another partner in his business, or the successor to whom he has sold his practice, will continue to hold the same office? What is the duty of his brother solicitors in the neighbourhood if the desire to invite candidates for the post, and to discriminate between the resulting claims, is manifested by advertisement? Should they compete against their professional friend, or should they allow the possible importation of an outsider? Similarly a medical man is officer to a municipal institution or some public authority—again, let us assume, with great credit to himself and benefit to the community; when he desires to let go of the appointment, ought he to consider that another practitioner in his firm, or the purchaser of his private practice, or of a share of that practice, has a right to succeed him? There is no doubt that the view held by many solicitors and medical practitioners is that a vested interest can be to some extent created by a record of good service, for in the sales of legal and medical practices the probable succession to public appointments is often mentioned as an inducement to purchasers. But there is also no doubt that, particularly of late years, the feeling of the public has been against the creation of any vested interest in public appointments; and State, county, and municipal authorities have with much more frequency begun to seek competitors for these posts by advertisement. When this is done the ensuing action of the local solicitors or medical practitioners will be dictated by local feeling, and inasmuch as this is not always unanimous in one place, or at all common in different places, professional troubles may arise.

The appointments as medical officer to a municipal fever hospital and to a borough police force recently became vacant in a medium-sized and prosperous town owing to the retirement of the senior partner in one of the medical firms. All the medical men in the town, we are informed—and this would mean between 30 and 40 practitioners—received official notice of the vacancies, with an intimation that they could apply for the posts. The chairman of the division of the British Medical Association was thereupon approached by several of the local practitioners, and asked to advise whether application for the posts in competition against the partner of the retiring holder would be an unprofessional act, it being easily ascertainable knowledge that that gentleman desired the succession. A meeting of the local practitioners was accordingly held, the election being postponed for the purpose by the municipal authorities, when it was decided that the medical profession should support the application for the posts of the retiring holder's partner, on the double ground that he had considerable experience of the work and that he had bought from his former senior partner these and other appointments. The next event might, we think, have been anticipated. The municipal committee entrusted with the election to the vacancies decided to advertise them, and, if necessary, to import a practitioner to serve the public interest. We are glad to think that this disagreeable position is not in the least likely now to be reached, for during the week a further meeting of the local practitioners has come to a decision that public appointments can no longer be regarded by medical men as vested interests. It will be open, therefore, as far as professional considerations go, for any medical man in the borough to apply for the vacant appointments.

It is in every way satisfactory that the medical profession and the public authorities should have avoided disagreement upon a delicate issue. On the one hand, it is a legitimate grievance of a medical practitioner, who in accordance with custom has anticipated election to such posts, that he should be passed over, and in the case in question it was believed that this would occur. But, on the other hand, the municipality was placed in an impossible situation if it was represented to them that posts in their gift must pass in accordance with some scheme of purchase whereby the public does not benefit. Those who buy medical practices or medical partnerships ought to know that they cannot secure in this way the reversion to public appointments, though they can obtain a very good chance of being chosen to fill the vacancies caused by the retirement of their predecessor. We have nothing but admiration for the spirit of unity that has animated the local profession in this town—they have stood by their brother practitioner where they considered it fair to do so. But a spirit of discretion has prevailed at the right moment. A position was reached in which professional codes and public interests were made to appear antagonistic, and on every ground the matter became one for amicable settlement. A municipality must be held at liberty to choose whom they consider likely to serve the public best. As no one can for a moment suppose that such a man is likely to be obtained by importation after advertisement, there must always be a sound basis upon which the local medical profession and civic authorities can come to an agreement.

A New Domestic Medicine and Some Ethical Points.

On Feb. 26th the first instalment of a fortnightly "encyclopædia" of medicine for family use was heralded by advertisements in lay newspapers and by means of leaflets inserted in cheap and popular magazines. Such a form of commercial enterprise seems no great novelty in these times, and might well be allowed to pass unnoticed, were it not for the objectionable publicity given by the publishers of this work to the names of a number of medical practitioners. As our correspondence columns show, this unauthorised advertisement of their names, qualifications, and appointments has aroused instant protests from some of those concerned. From the letters which we print this week, and from many others which we have received, it appears that the assistance given to the editor of the "encyclopædia" by medical practitioners was given on the understanding, explicit or implied, that no unprofessional use should be made of their names. The tenor of the communications which have reached us is to the effect that the various consultants lent their aid to a brother practitioner, in their private capacity, by looking over, and in some cases correcting, his written accounts of conditions of which he could not have a specialised knowledge.

The publishers, however, not being bound by any limitations, have fostered the sale of the work by extraordinary advertisements representing it to be the product of coöperation between the editor and "thirty eminent medical and surgical specialists." Worse than this, a review, written by a layman, appeared in the *Daily Mail* simultaneously with the publication of the first instalment of this encyclopædia; and this review, an astonishingly silly piece of writing, violated every canon of professional taste, mentioned consultants by name, and in some instances cordially recommended them to the public. A prefatory statement to the "Family Encyclopædia of Medicine" mentions Dr. HUGH H. RIDDLE as the editor, sets out the names of 32 physicians and surgeons from whom it is said assistance has been obtained in named subjects, and contains the following passage: "When approached by his publishers to compile a thoroughly up-to-date and instructive work on the modern scientific treatment of disease, which could be readily understood by the layman, the editor refused even to consider the possibility of attempting a task of such magnitude until he had assured himself of obtaining active cooperation and assistance from a large number of his friends and acquaintances, including the above distinguished members of the profession," who are thereupon thanked. Dr. RIDDLE'S letter in our columns regrets the unfortunate publicity given in advertisements to the names of those who helped him and admits the breach of medical ethics which has occurred. But he appears to have overlooked the fact that he has suggested in his preface that active coöperation was given him in the compilation of his encyclopædia by the 32 medical practitioners whose names are prominently given in that preface, together with their various and in some cases dignified posts attached. We can imagine that some of those who acceded to Dr. RIDDLE'S request for literary and scientific help will dislike this description of their action.

After all, it is the profession of medicine that is offended. Most of the 32 victims enjoy a position so good in the eyes of their fellow practitioners that it will be taken for granted that they have been exploited. They can afford, perhaps, to think that little harm has been done. But this is not the case. The public reading the advertisements of, and the prefatory statement to, the first issue of the "Family Encyclopædia of Medicine" will gather the impression that there is no professional objection to medical men giving their names to, and cooperating in the production of, a work directed to the public and intended to instruct the public upon matters of medical treatment. That is an impression which it is one of the duties of the General Medical Council to correct. We are happy to state that a meeting of the medical men concerned has been called to consider the concerted measures to be taken in the interests both of professional ethics and public policy.

Princely Generosity.

In the London press at the end of last week there was revealed to the world a secret which to some extent was no secret. For when some year ago Prince ALEXANDER of TECK, chairman of the charity, announced at a quarterly court of the Middlesex Hospital that a donor who desired to remain anonymous had given a sum of £10,000, and had later increased this to £15,000, towards the foundation of an Institute of Pathology in connexion with the hospital, a good many people said one to another—"That is BLAND-SUTTON." In moving the adoption of the annual report and accounts of the hospital at a court of governors held on Feb. 26th Prince ALEXANDER of TECK was able to read a letter publicly from Sir JOHN BLAND-SUTTON, who stated that he had preferred to remain anonymous at the outset so that in the needful preliminary work he might not seem to claim any peculiar influence, but as the chief points in the organisation of the institution have now been agreed upon by his colleagues the need for anonymity is gone. Sir JOHN BLAND-SUTTON has made one of the largest donations that has ever been made by any medical man during his lifetime to a medical cause, and we cannot sufficiently admire the simplicity and singleness of purpose which his gift has displayed. There are no sort of conditions attached, there are no sort of stipulations. The donor knew that the scheme which he was thus prepared splendidly to support was on right scientific lines, and felt sure that its future could be arranged so that it should continue on those lines; while the scientific work of his life made him see that in these days a pathological institute to work in harmony with the clinical labours of hospital wards is absolutely needed in the cause of medical progress.

Annotations.

"Ne quid nimis."

THE LISTER MEMORIAL FUND.

THE committee of the Lister Memorial Fund has commissioned Sir Thomas Brock, R.A., to execute a medallion portrait of the late Lord Lister, to be placed in Westminster Abbey. This will form part of the International Memorial to commemorate the priceless services of Lord Lister to the cause of science and the alleviation of human suffering. Further subscriptions are required to enable the committee to carry out adequately the proposed scheme for the establishment of an International Lister Memorial Fund for the advancement of surgery. Among the subscriptions recently received are the following: American Surgical Association, £135; received through Dr. W. W. Keen, of Philadelphia, £35 (second donation); committee of surgeons in Holland, £125; Faculty of Medicine, University of Copenhagen, £109; members of the medical profession in Victoria (Australia), £91; medical and surgical societies in Japan, £31; Union of Swedish Hospital Surgeons, £20; Newcastle-on-Tyne committee and members of the Clinical Society, £113; City of Belfast committee, £54. Donations may be sent to the honorary treasurers of the fund (Lord Rothschild and Sir Watson Cheyne) at the Royal Society, Burlington House, W.

THE SYNTHESIS OF FOODSTUFFS.

IT is noteworthy that while we hear on all sides of the triumphs of synthesis in the manufacture of certain industrial products no practical success has so far been obtained in producing foodstuffs by synthetic means; and yet the elementary foodstuffs are less complex in composition than, say, rubber, indigo, or the numerous aniline derivatives, and a splitting up of food substances into simpler compounds is easy. Starch, for example, the leading representative of the carbohydrates, is readily converted into oxalic acid by oxidation methods, as by treatment with nitric acid, while sugar readily yields carbon and water when warmed with strong sulphuric acid. But the reverse processes are not known; starch has not been artificially built up from oxalic acid or sugar from carbon and water. Certain attempts have been made to elaborate foodstuffs out of the simple materials carbon, water, and nitrogen, but with results of no practical significance. No laboratory has yet been able to reproduce the synthetic methods of the plant or animal. With all his wonderful constructive successes the chemist has not yet made bread or any constituent of it on a commercial scale from the elements which compose it. Starches, proteins, and fats in significant quantities are so far exclusively the products of plant and animal activities. Now and again it has been announced that a step forward towards synthetic foodstuffs has been made by employing chemical or electrical agencies, but such experiments have led to no practical development. Later it has been stated that the synthesis of certain organic compounds can be effected by photo energy. It is confidently asserted that the sugars can be built up from carbonic acid gas and water by exposing these simple compounds to the action of ultra-violet light. We have already referred to the interesting observation that the ultra-violet rays are capable of starting chemical changes analogous to those produced by ferments or enzymes. In this case it is clear that biological action has been dispensed with, so that we need not be without hope that the so-called vital agencies may prove after all not to be essential to the production of foodstuffs. It is further remarkable that the ultra-violet rays are capable of decomposing carbonic acid, inasmuch as chlorophyll, under the influence of the sun's rays, effects the same process in the plant. When we come to understand in more definite terms the chemistry of the cell the chances of producing foodstuffs by synthesis will unquestionably be improved.

THE TREATMENT OF LEPROSY BY CHAULMOOGRA OIL.

WE commented in THE LANCET of Sept. 27th, 1913, on two cases of apparent cure of leprosy by injections of chaulmoogra oil combined with camphor and resorcin given hypodermically. These cases were reported by Dr. Victor G. Heiser, from the San Lazaro Leper Hospital, Manila. It was then stated that there were in the same hospital at the time of writing "a number of other cases" under treatment which had for varying periods presented only negative evidence as regards leprosy, though all of them exhibited typical lesions when the treatment with chaulmoogra oil was begun. Dr. Heiser now[1] reports the discharge of two of these cases after having been free from leprosy for two years. In the first two cases reported the conclusions to be drawn were somewhat obscured by the fact that immediately on their admission to hospital both patients received vaccine treatment, so that it was impossible to determine what share, if any, this may have had on the subsequent improvement. The present cases, however, received no vaccine treatment. As in the former instance, both cases were mild. In both there were typical leprous macules and the diagnosis was confirmed by microscopical examination. The first patient began treatment with chaulmoogra oil by the mouth, in 10-drop doses three times a day, on Jan. 7th, 1911, but owing to gastric intolerance weekly hypodermic injections of the chaulmoogra oil, camphor, and resorcin formula were substituted on Feb. 15th. The dose began with 1 c.c. and was increased gradually to 10 c.c. by April 20th, when it was gradually decreased to 1 c.c., to be again gradually augmented to the maximum dose. Treatment was discontinued from Oct. 15th, 1911, when examinations of the patient proved microscopically negative, to Jan. 7th, 1913. Then it was recommenced, raised to the maximum, and again decreased. On Oct. 30th, 1913, microscopical evidence of the disease having been absent for two years and there being no clinical evidence of the disease then existing, the patient was discharged on probation as apparently cured. The other case was similar. The treatment by injection was begun on May 4th, 1911, the maximum dose of the injection reached, however, being only 5 c.c., as attempts at larger doses caused severe palpitations and præcordial distress. The macules began to improve a few weeks after treatment was begun, and had entirely disappeared by August 25th, 1911, since which time all examinations have proved microscopically negative. This patient was discharged on probation on Nov. 4th, 1913, being apparently free from all signs of the disease. These two further cases materially strengthen the argument against the cases being instances of the unaccountable spontaneous disappearance of the disease that does undoubtedly occur at times. As we understand that there are still other cases under treatment increasing interest will be evinced in this cumulative evidence of its value. A letter appears elsewhere in this issue of THE LANCET on the question of the identity of chaulmoogra oil.

GOLDSMITH'S MEDICAL CAREER.

THE proposal to set up in London a replica of Foley's fine statue of Oliver Goldsmith, which stands with that of Edmund Burke at the gateway of Trinity College, Dublin, should serve as a reminder that the great Irishman struggled in practice as a physician in London, and that he suffered many disappointments and privations before his final success in literature was achieved. Goldsmith reached London in February, 1756, after a somewhat mythical tour in France and Italy. He was then in a state of utter destitution, and with difficulty, we must suppose, managed to become a chemist's assistant on Fish-street Hill, near the Monument. Later on, through the kind help of a Dr. Sleigh, he set up as a physician upon the opposite side of the river. Here he told a friend that he "was doing very well," but he was in a tarnished dress and a shirt a fortnight old. Reynolds once told an anecdote of the care with which Goldsmith at this time carried his hat so as to hide a patch in his coat. He tried all kinds of other employments, from that of usher to that of printer's reader, but returned as a *pis aller* to the medical profession, for which he had so little gift and for which he was at this time not "qualified" as the word is now understood. In December, 1757, he writes to his brother-in-law Hodson that he was making shift to live by a "very little practice as a physician, and a very little reputation as a poet." In August, 1758, he wrote three letters to friends in Ireland, begging them to get him subscribers for his forthcoming book, "On the Present State of Taste and Literature in Europe." The MS. of one of these letters was reproduced in 1858 by the modern representative of Griffin, Goldsmith's original publisher. It probably has often been torn from the collected edition of Goldsmith printed by Griffin in 1858, and has deceived the unwary collector of autographs. In this letter, which is addressed at great length to Mrs. Lawler, *née* Contarine, the cousin with whom poor "Goldie" had been in love in Ireland, he gives an account of his penury, none the less poignant for its tone of persiflage. He intends, he says, to adorn his room with "maxims of frugality." "These," he continues, "will make pretty furniture enough and won't be a bit too expensive, for I shall draw them all out with my own hands, and my landlady's daughter shall frame them with the parings of my black waistcoat. Each maxim is to be inscribed on a sheet of clean paper and wrote with my best pen, of which the following will serve as a specimen. 'Look sharp. Mind the mean (*sic*) chance. Money is money now. If you have a thousand pound, you can put your hands by your sides and say you are worth a thousand pounds every day of the year. Take a farthing from an hundred pound, and it will be a hundred pound no longer.' Thus which way soever I turn my eyes they are sure to meet one of those friendly monitors, and as we are told of an actor who hung his room round with looking-glasses to correct the defects of his person, my apartment shall be furnished in a peculiar manner to correct the errors of my mind." The sale of his book was to pay for his passage to Coromandel, where, through his friend Milner, he had obtained the position of physician and surgeon to a factory. His practice was to bring him in £1000 per annum, but evidently he was expected to qualify first. He must have been familiar with Smollet's description of an examination at Surgeons' Hall in "Roderick Random," but undeterred by this he presented himself before the examiners and was disqualified. The examiners were probably Messrs. Mark Hawkins, Fullagar, Nourse, Girle, Singleton, and Roul. The entry in the Royal College of Surgeons "Examination Book" under date Dec. 21st, 1758, states that before a Court of Examiners, held at the theatre, James Johnson was "appointed apprentice to Mr. Carson, Thomas Meggs qualified for surgeon to a regiment, James Bernard Mate to an hospital, Oliver Goldsmith, found not qualifyd for Do." At the same court four naval surgeons were also appointed. The poet, we now know, afterwards obtained the M.B. of Dublin (probably before 1761), and of Oxford in 1769.[1] His medical career in London, however, seems to have ended with his failure at the Royal College of Surgeons of England. He became famous in literature, even at a time when he was playing the flute to the ragged children at the foot of Breakneck Steps leading to his lodgings in Green Arbour Court. Sixty-eight pages are now devoted to his works in the British Museum Catalogue.

ENLARGEMENT OF THE SPLEEN IN EGYPT AND ITS SURGICAL TREATMENT.

IN the *British Journal of Surgery* for January there is one contribution possessing an interest that is wider than that of a purely surgical article. Professor Owen Richards, of Cairo, reminds us of the frequent occurrence of a very interesting form of splenomegaly among Egyptians, and gives a summary of the results achieved in 22 cases by splenectomy. The clinical features of this disease are such as to range it alongside of the syndrome usually described as Banti's disease, but it is in itself so definite a malady that Professor Richards prefers to retain for it a separate title—Egyptian splenomegaly. All of his 22 patients, with three exceptions, were males, and all belonged to the labouring class. Nearly always the symptom that brought them to seek advice was abdominal enlargement, which eventually reaches considerable proportions, as the admirable photographs illustrating the article prove. There is usually a history of fever in attacks which immediately precede the splenic enlargement. The other constant features of the disease are anæmia and cirrhosis of the liver often associated with ascites. With four exceptions, all the patients came for admission to hospital during the hot season. It is the hepatic lesion, with the malnutrition which it induces, that leads eventually to a fatal issue. Hæmatemesis is rare. The pathological change in the spleen, portrayed in some excellent microphotographs by Professor A. R. Ferguson, is a general hyperplasia, while the hepatic lesion is a monolobular cirrhosis. The probability of an infective origin is so obvious that this causation may be assumed, even though no parasite or bacterium has as yet been incriminated. Drug treatment, with quinine and salvarsan, has been unsuccessful. Of the 22 cases subjected to splenectomy, 4 ended fatally before the patients left hospital; in 2 of these extreme ascites was present, and this, in Professor Richards's opinion, constitutes a definite contra-indication to splenectomy. In 2 cases it was found impossible to complete the operation, but both patients recovered sufficiently to go home, one of them dying six months later. Of the others, the results in the first 10 cases are specially emphasised. One died five months after operation, the cause being unknown; 3 others could not be traced; and 6 were alive and well from nine months to two and a half years after operation. "Broadly," says Professor Richards, "the cases most suited for operation are those with big spleens and big livers, in which the disease is severe and progressive, but which have not yet reached the stage of ascites." Patients should be prepared for operation by a preliminary course of rest in bed, treatment of ankylostomiasis, and full diet, with drugs to counteract the anæmia. Operations to cure the ascites have without exception ended in disappointment. A full account of operative technique is given. The average weight of the excised spleen is about 3 lb. The chief operative risk is hæmorrhage, best avoided by systematic division of individual vessels between ligatures.

GREEK AND ROMAN MEDICINE.

THE present year has seen already the issue of two works in the English tongue dealing with the history of medicine—the one a survey of the whole subject, from the pen of Dr. Fielding Garrison, principal assistant librarian of the Surgeon-General's Office, Washington, a monumental work; and the other a small book dealing only with Greek and Roman medicine, by Dr. James Sands Elliott, of Wellington, New Zealand.[1] To give a full account of medicine during even this comparatively short period of history (say, 2000 years) would entail the writing of a large work, and Dr. Elliott has wisely attempted only a sketch of the subject. By an inversion of history, of which he is fully aware, he begins with early Roman medicine and then goes back to Greek medicine, of which he gives an account down to the time of Serapion, of Alexandria, circa 280 B.C. The course of Roman medicine is then resumed and continued as far as a practitioner of the sixth century A.D.—namely, Paulus Aegineta, who was the last important member of the great school of Alexandria. If we may judge by most extant literature on the subject the art of medicine and its practitioners were not held in high estimation in Rome. Medical men were nearly all foreigners and mainly Greeks, hence the abuse which Cato and the elder Pliny poured upon them. It must be allowed that in many cases the medical man was very ignorant and illiterate, and that often the line between the quack and the trained practitioner was very narrow. But the coarse insinuations of Martial, Juvenal, and Petronius against the profession are probably no more true pictures of it as a body than the diatribes which used to appear in the political press about medical men in the early days of the Insurance Act. Seneca, in his treatise "De Beneficiis," writes with real good feeling of the medical man, and practitioners like the Stertinii enjoyed the confidence of the Cæsars and made enormous fortunes, though, of course, this latter fact does not necessarily mean that they were able practitioners, for quacks made as much or even more money than educated physicians in the heyday of Roman luxury. In his account of early Roman medicine Dr. Elliott speaks of Livy as saying that Numa Pompilius was struck by lightning and killed as the result of experiments in physical science, and that these experiments have been conjectured by some to have been electrical. This is an error; it was Tullus Hostilius and not Numa whom Livy describes (apparently on the authority of L. Piso) as being killed by lightning, and the "experiments" were religious conjurations which he was trying to perform after a formula left behind by Numa for bringing down lightning from heaven. Rain bringers or lightning bringers are found among savage medicine men to-day, and the story of Numa, together with those of Salmoneus and Remulus Silvius, the last two of whom were killed in the same way as Tullus, are evidently traditions of this kind of magic. It is not a wholly impossible point of view to suggest that these stories arose from there having been some daring investigator in primitive times who tried something analogous to Franklin's well-known experiment on atmospheric electricity with the kite. One of Franklin's followers tried the same experiment and was killed. The Etruscans studied lightning with assiduity, and Numa, who was a Sabine, was traditionally learned in natural philosophy; so he may have succeeded where others failed. This, however, is speculation, whereas Dr. Elliott, in his interesting little work, has collected many facts of value to the medical historian.

INJURY TO THE DESCENDING PORTION OF THE DUODENUM DURING REMOVAL OF THE RIGHT KIDNEY.

IN the *Journal of the American Medical Association* of Jan. 31st Dr. William J. Mayo has called attention to a serious injury to the descending portion of the duodenum—apparently previously unreported—which may occur during removal of the right kidney if infiltration about the pedicle of the kidney has caused close adhesion to the duodenum. It may be remembered that the duodenum in its descending course overlies the pedicle of the right kidney and a considerable portion of the inner part of the lower half of that organ. As this portion of the duodenum is retroperitoneal and more or less fixed, the accident is readily understood. During right nephrectomy the pedicle is loosened until it can be well surrounded with the fingers, clamped with forceps or tied, and as long as this method is followed the duodenum will not be injured. But when, on account of infiltration, such a pedicle cannot be formed the vessels may be torn with a resultant gush of blood, or, after removal of the kidney, the pedicle may retract from the forceps or ligature with sudden hæmorrhage. In the attempt to check this by grasping the vessels with forceps having strong biting jaws the duodenum may be seized. As a rule, the result is not manifest for several days. The injured part of the duodenum becomes necrotic and a duodenal fistula ensues. Dr. Mayo has known of three such cases. The first occurred many years ago when he was assisting a surgeon who was following nephrotomy by nephrectomy. Heavy biting forceps were left on the pedicle. On the fourth or fifth day began a copious discharge of biliary and pancreatic secretions and of food almost as soon as taken. The patient rapidly became exhausted and died in two weeks. In the second case a carcinoma of the renal pelvis was being removed, the result of irritation by a branched stone. The pedicle was extremely rigid from carcinomatous infiltration. In the attempt to remove it the vessels were torn across. With considerable difficulty they were caught by heavy toothed forceps, which were left *in situ*. On the fifth day a duodenal fistula was manifest. Biliary and pancreatic secretion and intestinal juices were passed in large quantities. The patient, already in a serious condition, developed acute nephritis in the remaining kidney and died from asthenia on the tenth day. The necropsy showed a large fistulous opening in the descending portion of the duodenum. The third case was one of duodenal fistula following nephrectomy and was seen in consultation. The pedicle had been infiltrated with inflammatory products and the kidney had torn across. The duodenum was injured in the application of heavy forceps. The fistula was small at first but gradually enlarged and the patient died two weeks after operation. A feature of all the cases was great irritation of the skin by the escaping secretions. In one case this set up eczema, which rapidly spread to a great part of the body. Another structure that is even more frequently injured in the same manner is the vena cava. When the renal pedicle is infiltrated the renal veins may tear away from the vena cava and the latter may be grasped in the forceps used to stop the bleeding. Since the occurrence of the second case Dr. Mayo has avoided the use of forceps in the first attempt to control the bleeding; he finds that they are seldom necessary. The fingers are so sure a means of temporary hæmostasis that they should be relied on and the forceps used only to clamp the vessels after they have been caught. With an adequate incision for the removal of the kidney, Dr. Mayo considers that injuries to the duodenum or failure accurately to secure the vessels will seldom occur. In two classes of cases, however, injuries to the duodenum, as well as to the vena cava, are liable to occur. When fixation and shortening of the pedicle takes place as the result of inflammation, usually in cases of pyonephrosis with stone, and especially following nephrotomy for such a condition, the attempt to remove the kidney in the ordinary manner renders accidents in securing the pedicle not infrequent. Tuffier's subcapsular nephrectomy is the proper procedure. In removal of carcinoma of the renal pelvis injuries to the duodenum are liable to occur. Here subcapsular nephrectomy would be inadequate, and the duodenum will be endangered by the most expert and careful surgery. When it becomes manifest that the accident to the duodenum has occurred Dr. Mayo would, before the patient is exhausted, make a transperitoneal attack on the fistula, lift the descending duodenum from its bed, suture the opening, transplant a flap of peritoneum or omentum across the suture line, and finally perform jejunostomy for temporary feeding purposes.

[1] Outlines of Greek and Roman Medicine. By James Sands Elliott, M.D., Ch.B. Edin., editor of the New Zealand Medical Journal. London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 165. Price 7*s.* 6*d.* net.

THE ALLEGED SPREAD OF LEPROSY IN THE UNITED STATES.

FROM time to time waves of alarm respecting leprosy sweep over certain countries and create considerable disquietude in the minds of the public. There has been evidence of late, for example, in France concerning this question, and in official circles there it has been seriously debated whether an active campaign against the disease should not be undertaken forthwith under Government direction, more especially in regard of imported cases.[1] In the United States of America the same uneasiness respecting the importation of leprosy has recently been manifested, and our contemporary the *American Journal of Tropical Diseases and Preventive Medicine*, the official organ of the American Society of Tropical Medicine, has voiced this fear in an editorial published in the last issued number (Vol. I., No. 6). The writer of this, Dr. Isadore Dyer, one of the editors, in discussing the duty of the Federal Government regarding leprosy, deplores the lack of interest displayed by Members of Congress upon the subject. It is true that these members will promptly, when requested, sanction the expenditure of comparatively large sums of money for the treatment and prevention of the disease as well as for its experimental investigation in the American colonies and tributary islands; but when similar demands are made for funds to prevent the spread of the disease at home and for the scientific study of its etiology and treatment, the applications are met with apathy and indifference and the subject is allowed to drop. Only three States—namely, Louisiana, Massachusetts, and California—have so far adopted methods for the control of lepers by the State, although in nearly one-third of all the States comprised within the Union leprosy is known to exist in varying amounts; in some of them the need for State control is said to be very urgent. Fears are expressed that if the Federal Government does not intervene to deal satisfactorily with leprosy the danger will before long become universal. The United States are in frequent communication through shipping with countries where leprosy is widely prevalent, and inquiries have shown that in some ports of the United States foreign lepers have little difficulty in effecting a landing and passing thence into the interior, where they are soon lost sight of, but where they may spread the infection unobserved. This source of danger is stated to be rapidly increasing. Leprosy is known to be common in some of the foreign possessions and dependencies of the United States—e.g., the Hawaiian Islands, the Philippines (where at present some 5000 lepers are under supervision), and Porto Rico. Central America and the whole of the west coast of South America are reported to be full of the disease. Colombia, for instance, of which the Panama Canal Zone once formed a part before being taken over by the United States, was the seat of an inquiry recently, which revealed the fact that no fewer than 20,000 lepers existed in that country. According to Dr. Dyer, the United States is the only Government of any importance that does nothing towards the treatment and prevention of leprosy within its own borders at home, and he therefore urges Congress to deal with the matter before it is too late. We think that perhaps Dr. Dyer and his supporters are inclined to take a too gloomy view of the situation. It is believed at the present time by many experts that leprosy is only feebly contagious, and that for the propagation of the infection a very unhygienic environment is necessary. In Europe the disappearance of the disease has been associated with the removal of overcrowding of dwellings, the keeping of houses and persons in a cleanly condition, and the securing that human food shall be good in quality as well as sufficient in quantity, and if cases of leprosy are imported they must be treated under conditions of strict surgical cleanliness. When these points are carefully attended to there seems little likelihood that leprosy will spread, more especially in countries which possess efficient sanitary administration.

INFECTION WITH THE BOVINE TUBERCLE BACILLUS.

THE communicability of the bovine tuberculous viruses from animal to man has been definitely proved, but the frequency with which such an infection takes place still gives rise to much difference of opinion. The majority of observers maintain that pulmonary tuberculosis is generally due to the human bacillus, being rarely caused by the bovine type, but that tuberculosis of the glands and joints is relatively more frequently brought about by the bovine virus. Evidence is now accumulating that when the joints (including the spine) are affected the human bacillus is most commonly concerned. With regard to glandular tuberculosis, the results obtained by different investigators have varied, but in this case again the predominant opinion appears now to be that the human bacillus is more often the causal agent. In the *British Medical Journal* of Jan. 17th of this year Dr. A. Philp Mitchell (Edinburgh) published an interesting "Report on the Infection of Children with the Bovine Tubercle Bacillus." After giving a description of the technique which he has employed for the cultivation of the bacilli and the methods of distinguishing the types of bacilli, he lays down the conclusions at which he has arrived. His material was derived from 72 consecutive cases of tuberculous cervical glands in children; of these 38 resided in Edinburgh and 34 came from neighbouring country districts (within a radius of 30 miles). Out of these 72 cases, in 65 instances (90 per cent.) the bovine bacillus was present, and in 7 cases (10 per cent.) the human bacillus. This is a remarkable result, and Dr. Mitchell acknowledges that it is widely different from that obtained by investigators in other countries, but he maintains that it can be verified by the recognition of several correlative factors. These are: (1) the age of the patients (he believes that the importance of examining a large number of consecutive cases of tuberculosis of the cervical glands in young children has not been sufficiently insisted on); (2) in none of the cases of bovine infection was a family history of tuberculosis noted; (3) the almost universal practice in Scotland of feeding children with unsterilised cow's milk; (4) the great prevalence in Scotland of tuberculosis in dairy cows, and in conjunction with this he draws attention to the present very inadequate veterinary inspection and the ignorance of the dairy farmers in matters relating to bovine tuberculosis; (5) the fact that about two-thirds of the Edinburgh daily milk-supply comes from small byres situated in rural districts round the city, where there is practically no supervision. These are important observations, the significance of which would be rendered much stronger if the suggestions are in the future corroborated by other workers, for if infection of the cervical glands in children is frequently acquired from a bovine source, legislation is imperative to protect the children, and Dr. Mitchell emphasises his contention that until such measures are obtained cow's milk should always be sterilised before being given to children. It will be interesting to see whether these conclusions are contested or supported by other investigators. They require most careful consideration.

ACUTE RHEUMATISM LOCALISED TO A PARALYSED LIMB.

IN a recent annotation[1] we called attention to a case reported to the Société Médicale des Hôpitaux of Paris in which chronic periarthritis of the hand followed herpes zoster of its dorsal aspect and of the forearm. From the beginning the patient complained of stiffness in the finger-joints. When the pain ceased the stiffness remained. After two years there was some improvement, but the hand could not be shut. Other French cases—arthropathy of the hand localised to the area supplied by the affected nerve root and two cases of zona of the upper limb followed by lesions resembling arthritis deformans—were mentioned. In a letter published in our columns on Jan. 10th last Dr. P. W. Latham stated that these cases seemed to illustrate and confirm in a remarkable manner the view, which he had held for many years, that "the progress of arthritis deformans is associated with and dependent upon irritative or destructive lesions of the anterior cornua of the spinal cord, the lesions being especially marked in the cervical and lumbar enlargements." He thought that in some of the cases of herpes zoster the irritation caused by the changes in the ganglion cells of the posterior roots might give rise to changes in the ganglion cells of the anterior horns and in the anterior nerve roots. In this way the nutrition of the muscles, bones, and joints, over which the ganglion cells of the anterior horns are supposed to exercise a controlling influence, would be modified and rheumatoid arthritis produced in the limb to which the affected nerve was distributed. At a meeting of the Société Médicale des Hôpitaux of Paris on Jan. 29th M. Georges Guillain and M. Jean Dubois reported a case which bears out the general doctrine of the dependency of arthropathy on nerve influence all the better as it was of quite a different kind, for there was not nerve irritation, but the withdrawal of nerve influence which evidently favoured the attack of the microbe of acute rheumatism. The patient was a man, aged 50 years, who had suffered from acute rheumatism 15 years previously. He fell and dislocated his right shoulder. Reduction was performed at the Necker

---

[1] THE LANCET, Nov. 29th, 1913, p. 1560.

Hospital. Paralysis, most marked in the hand but involving the whole limb, followed. The only sensory trouble was a slight band of hypoæsthesia at the external border of the arm. There was a partial reaction of degeneration in all the muscles, increasing towards the extremity of the limb. Eight days after the accident acute polyarticular rheumatism occurred and was localised to all the fingers of the right hand and the right elbow. The joints were swollen and very painful, and the overlying skin was œdematous, preventing any passive movement. Under aspirin the attack passed off in ten days. The case is an excellent example of the localisation of an infection in an area of which the nerves are injured.

AT a meeting of Fellows of the Royal College of Surgeons of England held in Manchester on Feb. 25th, it was resolved that it is advisable that a member of the Manchester Medical School should be a candidate for the next ensuing vacancy on the Council of the Royal College of Surgeons of England, and it was agreed to nominate Professor W. Thorburn, senior surgeon to the Royal Infirmary.

THE Schorstein Memorial Lectures at the London Hospital Medical College will be delivered on Thursdays, March 19th and 26th, at 4.15 P.M., in the anatomical theatre, by Dr. Henry Head, F.R.S., physician to the hospital, who will take as his subject the Clinical Aspect of Syphilis of the Nervous System. Members of the medical profession are cordially invited to attend.

AMONG the 15 candidates who have been recommended by the Council of the Royal Society for election as Fellows are the following members of the medical profession: Dr. Arthur Edwin Boycott, professor of pathology in the University of Manchester; Dr. Henry Hallett Dale, director of the Wellcome Physiological Research Laboratories; and Dr. Diarmid Noël Paton, Regius professor of physiology in the University of Glasgow.

IT has now been settled that the dinner to Surgeon-General Gorgas and his assistants will be held on Monday, March 23rd, at 8 P.M., at the Savoy Hotel. We hope to learn that a good muster of the medical profession will take place on the occasion. The work done by Surgeon-General Gorgas and his staff in the Sanitary Department at Panama is famous throughout the world, and ought to receive from the medical profession of this country an enthusiastic endorsement.

UNIVERSITY OF LONDON.—Dr. F. H. Thiele, lecturer in bacteriology and immunity at University College Hospital Medical School and pathologist to University College Hospital, and Dr. Bernard Hart, lecturer on mental disease at University College Hospital Medical School, have been elected Fellows of University College. Dr. Peter Thompson, professor of anatomy in the University of Birmingham, has been elected a Fellow of King's College.—The twenty-first anniversary of the Union Society of University College will be celebrated on Thursday, March 19th, when the Foundation Oration will be delivered at 8.30 o'clock by Sir Edward A. Schäfer, F.R.S., professor of physiology in the University of Edinburgh, and first president of the society. The subject of the oration is Certain Desirable Adjuncts to a University Education. Academic dress will be worn, and there will be a reception and concert at 9.30 P.M.

ANNUAL REPORT FOR 1912 OF THE CHIEF MEDICAL OFFICER OF THE BOARD OF EDUCATION.

READING the last report of Sir George Newman, chief medical officer of the Board of Education, the mind turns for comparison to a general planning and directing the advance of an army. In the beginning come skirmishing paragraphs dealing with details in a manner designed to produce their effect but followed by a series of 16 solid divisions, each treating of some special section of the work, detailing the way in which the heavy fighting is done. In the "Conclusion" the general surveys the course of events, speaks of the issue of the fighting, and of the future. The whole effect of the report is one of simplicity and lucidity, which is attained not only by the presentation of facts but by the suppression of others which can be treated at another time. Yet so comprehensive is the scope of the report that we realise that the subject of school furniture gets hardly a mention with a shock of surprise.

In the "Conclusion" Sir George Newman says that "Medicine is the servant and not the master of education," but his conception of service is that of a great leader serving a great purpose. Medical inspection is "contributory to the larger business of education, it is also closely bound up with the work of public health," which again is only one part of "the apparatus of national welfare." Even the choice of words, "larger business of education," "*apparatus* of national welfare," shows the mind thinking in terms of big issues. We could wish that this way of handling big issues could be transferred more universally to the school medical service in all parts of the country. In some areas these conceptions do prevail and the work is moulded on them, but in others, those, for instance, from which are sent up the "almost worthless" reports, as the Board of Education stigmatises them, the medical inspection work is looked at from a narrow parochial standpoint. Let those parochial areas see themselves as they are, parts of the nation, and the work they are doing (monotonously routine although much of it may be) as part of a great national work, and not only will they see more truly but do their work better. As Sir George Newman says, "the local education authorities who take the widest and truest view of school hygiene and its responsibilities and possibilities are likely to secure not only the best medical officers but the most capable and enlightened service from those officers." Reference is also made to the value of "a reasonable variety of work" and "ample opportunities for research and inquiry," and local education authorities are urged to encourage their officers to undertake special practical inquiries.

All the 317 local education authorities have now in being machinery of a more or less complete kind for the medical inspection of the million and a half children it is annually necessary to provide for out of a school population of six millions. 1111 school medical officers and 742 school nurses are employed in the work, the teachers, without whom the work could not go on, coöperate heartily for the most part, while there is a large army of voluntary and associated workers more or less directly concerned in inspection and "following-up" work with reference to treatment. 241 of the education authorities have appointed the school nurses above mentioned, and in some cases they also act as school attendance officers.

The Province of the School Medical Officer.

Medical inspection is at present compulsory for the groups of "entrants" and "leavers" only, but in 1915 the Board of Education will demand inspection of an intermediate group. This intermediate age-group inspection is already carried out by 120 education authorities, and some have even examined all the children in their schools. In addition 122 secondary schools, about one-eighth of the total number upon which grant is paid, have been inspected. Children selected by teachers or others on account of some presumed defect for examination as "specials" account for another considerable addition to the routine, as do the special inquiries also. Of these latter, 38 examples are given (many of which have already been called attention to in reviews of the report of school medical officers published in THE LANCET), and cover subjects so diverse as night-sweating, nervous children, pigmentation of eyes and hair, the physical conditions associated with backwardness, heart affections, the relationship between enlarged tonsils and dental caries, the temperatures of school children, the fitting of school children's spectacles and the condition in which they are kept, ringworm "epidemic" schools, vision and vision-testing, and the health of red-haired children.

The field of operations of the school medical officer is thus a wide one, and one to which adjacent territory must in the nature of things be annexed as time goes on. The scope of school medical inspection itself widens, and to inspection must be added questions having reference to treatment, sanitation of schools, special schools for mentally and physically defective children, the teaching of hygiene and physical training, the feeding of school children, and employment during and after school life; for all of these are matters "so closely related to and so vitally connected with the physical condition of the child that it is desirable in all educational areas that they should be referred more or less directly to the school medical officer for advice." Sir George Newman also enumerates 15 Acts of Parliament upon which the school medical officer should be prepared to advise his authority in so far as they affect children's health; they range from the Public Health Act, 1875, to the Mental Deficiency Act, 1913, and include the Factory and Workshop Act, 1901, and the Labour Exchanges Act, 1909.

It is satisfactory to note that as the scope of the work increases the understanding of it by the general public and the coöperation with it by the parents of elementary school children improve on the whole. There are now extremely few "objections" to medical inspection, although the number of parents who attend varies much in different places. The report suggests that this is dependent upon the cordiality of the invitation and many other circumstances. The percentages (approximate) of parents attending vary from 10 per cent. in Denbighshire and Staffordshire to 76 per cent. in Berkshire and 81 per cent. in Hertfordshire, from 27 per cent. in East Ham to 75 per cent. in Exeter and 91 per cent. in Wolverhampton. On the value of parents attending at inspections and getting a medical opinion first hand there is probably not much doubt, but the possibility of this will depend on the nature of the parents' employment and distance of the school from the home among other factors.

The Private Practitioner and the School Medical Officer.

An interesting section reviews the relationship of the private practitioner and the School Medical Service and makes clear the attitude of the Board. It is shown that this service includes the work of the general practitioner, "though always within the ambit of the organisation for the administration of which the school medical officer is and must be responsible." The parts played by the general practitioner include part-time medical inspection, treatment in private practice of conditions discovered at inspection, treatment at upwards of 300 hospitals, and a small amount of treatment under the Poor-law. In addition treatment at school clinics has been given by 112 part-time medical officers and 70 dentists who were engaged in private practice also in the same areas; this, of course, in addition to school clinic treatment by whole-time officers. Private practitioners further come into the school medical organisation as medical officers of training colleges, of special schools, and as nominated under the Elementary School Teachers' (Superannuation) Act. While the school medical officer must necessarily be held responsible for the general supervision of the organisation, he does not interfere with the actual details of treatment nor come between the private practitioner and his patient, but he or his assistant inspects the child and in one way or another brings the patient to the doctor.

The School Clinic.

An increasingly important part is played by the school clinic, and with the increase of these institutions there goes a corresponding increase in the efficiency of treatment of school defects as a whole. There are now 97 authorities which provide medical treatment themselves, and 61 of these include dental treatment. London has 23 treatment centres and provides for 84,000 children annually. The County of Essex has eight centres, four being dental clinics; Birmingham has seven centres, Newcastle-upon-Tyne has three clinics, and Leicester has two. But the school clinic is not the only treatment agency the efficiency of which is being increased, and is by no means the only agency considered by the Board of Education in allocating treatment grants. For, as Sir George Newman points out, when the Board take into consideration the scope, character, and efficient working of the authority's provision and arrangements for securing the medical treatment of cases requiring it, this does not necessarily mean that the authority should themselves provide treatment. "*The essential thing is that the ailing child should obtain adequate treatment.*" (The italics are in the report.) However this result is efficiently secured it must be good. But if when all arrangements have been made any considerable proportion of the children remain untreated, it will be for the authority themselves to consider the necessary treatment.

Apart from school clinics other arrangements for treatment may be grouped under: (1) Employment of school nurses; (2) systematic provision of spectacles; (3) organised treatment of ringworm; and (4) contributions to hospitals 241 education authorities employ school nurses, 101 provide spectacles, and 37 contribute to hospitals. In considering grants for treatment the general efficiency of the school medical service as a whole is also considered.

The total number of authorities to whom a grant was made was 229, 45 counties, 65 county boroughs, 84 non-county boroughs, and 35 urban districts; the amount of the expenditure on which grants were paid was £78,016 15*s.* 2*d.* Of this £23,985 14*s.* 1*d.* were for medical treatment, £49,934 4*s.* 6*d.* were for ancillary work, and £4,096 16*s.* 7*d.* for the cleansing of verminous children. Among the largest grants made by the Board were, London £12,958 8*s.* 10*d.*, Sheffield £1502 4*s.* 6*d.*, Derbyshire £1315 17*s.* 11*d.*, and Bradford £1000 6*s.*, and the amount of the grant in some cases formed a very substantial part of the total expenditure.

The Cleanliness of the Child.

A large share of time and thought is still taken up with the consideration of verminous conditions, and the conscience of many parents has still to be awakened to the fact that filthy conditions are also very unwholesome. Nevertheless, substantial progress is being made. The London County Council cleansing scheme, which has served as a model to other authorities, is considered and described at some length. The number of cleansing stations now in use in London is 21, and the increase in the scope of the work is indicated in the figures for 1911, when 251,592 children were examined, and in 1912, when 630,359 were dealt with. In some areas the percentage of verminous children has fallen in the last five years from 22·0 to 12·75 (Berkshire), from 24·9 to 2·3 (Aberdare), and in the last four years from 31·1 to 5·1 (York). In a few areas increase has been noted, but this is ascribed to increased vigilance. In the Isle of Wight Dr. Walker has published a list of schools "in order of merit," *pour encourager les autres.*

Shower-baths are beginning to be introduced into the schools, but the provision is very slight in England as compared with some foreign countries. Only 20 education authorities (out of 317) possess school baths. Considering how difficult it is to teach the young of the upper and middle classes to be clean, with the aid of bathrooms and servants, and considering that the "morning tub" is popularly believed to be one of our national subjects of conversation, it is a little curious that the school bath, in which cleanliness could be taught, does not make more headway.

Defective Vision.

One of the ways in which school hygiene can be of most service is in preventing avoidable visual defect arising from causes within the control of the school organisation. No more damning commentary on the schools of this country could be penned than the sentence in this present report, which states that "the examination by Snellen's test-types is still hampered by bad lighting in the case of many schools. In Cumberland and elsewhere it appears that in a great number of schools the illumination is so poor that it has been impossible to test the vision of children within the school." In schools where the lighting is thus defective the eyesight of the children is being destroyed by a compulsory education from which they cannot escape. It is earnestly to be hoped that the Board of Education will use their powers to the full to bring this state of things to an end at the very earliest possible moment.

An account is given of an investigation into 1907 cases of visual defect by Mr. N. Bishop Harman in London. The investigation was carried out at the school clinic at Belgrave Hospital for Children, Clapham-road. 1670 cases were actually available for classification, and of these 781 were boys and 889 were girls. Of the total number (about) 80 per cent. were refraction cases and (about) 20 per cent. diseased conditions of the eye, and the figures give a useful index of the proportions any education authority may find itself called on to treat. Mr. Harman divides the 1420 refraction cases into eight groups, which can be considered as belonging 66 per cent. to the section of hypermetropia and 34 per cent. to that of myopia. Of the total cases, 16·2 per cent. (231 cases) had an error of refraction of 5 dioptres or more, 14·0 per cent. (199 cases) suffered from squint, 166 of these being convergent squint. The importance of good lighting (both natural and artificial) is considered at some length, and an important point brought out with regard to the necessity for resting the eyes by far vision. For the purpose of securing this rest the windows should be brought down to a level at or near that of the children's heads so that their eyes may from time to time rest on some object outside the schoolroom. There appears here something more than the germ of an interesting divergence of view between doctor and teacher!

The interim report of a committee of the Illuminating Engineering Society on artificial lighting is reproduced and commended to the attention of school managers and of local education authorities and their officers, as is also the report on school books in the 1911 report. This section does not seem strong enough, and we should like to see the Board of Education taking up a much firmer attitude on sewing in schools and on the type of school books. The report of the British Association Committee has put the question of the permissible type in school books on to a definite basis. Much is being done to treat visual defects, but it would be very much better national economy to prevent them.

(*To be continued.*)

Public Health.

ANNUAL REPORT OF THE INSPECTOR-GENERAL OF HOSPITALS AND CHIEF HEALTH OFFICER OF NEW ZEALAND.

AN instructive report for the year ended March 31st, 1913, has been submitted by Mr. T. H. A. Valintine, the chief health officer, to the Minister of the Department of Public Health, Hospitals, and Charitable Aid. Public health work in New Zealand is undertaken both by local and central authorities, but the direction and supervision of much of the work, particularly in regard to general and special hospitals, is considerably more centralised than is the case in England. The population of New Zealand is slightly over a million; the 1912 birth rate was 26·48, and the death-rate—the lowest hitherto recorded—was only 8·87. Among classes of deaths usually contributing to high mortality we find an infant death-rate of 51 per 1000 births, about half the English rate, while the phthisis mortality is also in about the same proportion—0·5 per 1000 of population. Death-rates from cancer and arterial diseases, on the other hand, are nearer to those for England and Wales, and are stationary or on the increase. A comparatively high mortality from organic heart disease (1·2 per 1000) is noticeable. In regard to tuberculosis, it is stated that 231 beds will shortly be available in special sanatoriums for consumptive patients. Farm and labour colonies for suitable cases have also been proposed, but progress with these institutions is unlikely in view of the serious demands which hospital expenditure generally has been making on public funds. A system of medical inspection of school children was decided upon in May, 1912, and a preliminary survey has been undertaken. The result, as in England, has shown that a larger number of children require treatment for illness or defect than was originally anticipated, and a considerable increase of central and local medical staffs for the purpose is considered necessary. An attempt has been made during the year to reorganise the native medical service, which hitherto appears to have been carried out on the system of giving small subsidies to medical men to undertake duties of medical practice among Maoris, which have been very ill-defined. The quarantine stations of the Dominion are reported to be in several respects out of date and likely to be quite insufficient "for the accommodation of the ship's company of a modern liner." This conception of the provision needed by the sanitary authority of a port is foreign to English ideas on the subject, as in this country it is usually considered sufficient to allow the healthy passengers and crew to go to their destinations, these being kept under observation by the local sanitary officers. Probably the apprehension of small-pox has caused the more extensive provision of quarantine accommodation to be entertained. From the reports of the medical inspectors of schools it would appear that only some 5 per cent. of the children examined have been vaccinated, and the danger of the introduction of an unrecognised small-pox case into the more thickly populated parts of the Dominion is naturally viewed with considerable alarm.

The year has seen the greatest advance in the administration of the New Zealand Sale of Food and Drugs Act since its passing in 1907. An extensive set of regulations has been made providing for the proper labelling of food packages; for a statement of weight of the contents; limiting the use of preservatives, flavouring, and artificial colouring matters; and for the protection of food from contamination. These regulations represent a considerable advance and are worthy of imitation, or at least of close attention and study, outside New Zealand. For the greater number of foodstuffs in ordinary household use standards have been prescribed, and conditions have been laid down for securing the cleanliness and freedom from contamination of meat products, milk, ice-cream, and ices. The "fraud of the label" has been very prominently brought out as a result of these regulations in connexion with a large variety of foods, and the insistence on the law requiring reasonable accuracy of statement cannot fail to have beneficial results to the public. It may be noted that patent or proprietary "medicines" containing alcohol must now be sold under labels stating the percentage of proof spirit which they contain.

Some interesting figures are given in regard to the organisation for hospitals and charitable aid throughout the Dominion, and a series of detailed reports relating to these institutions, obtained by inspectors of the central department, is contained in the volume. The total expenditure of the hospital and charitable aid boards during the year 1912–13 was £469,787, of which no less than £228,337 was in respect of hospital maintenance. The former sum represents about 9*s.* 6*d.* per head of population, and has steadily increased since 1902–03, when the corresponding incidence per head was 5*s.* 10*d.* Ten years ago, however, only 18·2 per 1000 of the population availed themselves of hospital treatment, as against 25·8 per 1000 last year. The number of beds available per 1000 of the population is now 3·03. The cost of the service, which apparently provides hospital accommodation for diseases and accidents of all kinds, is defrayed from Government contributions, levies on local authorities, payments by hospital patients, and voluntary contributions. The latter have a decidedly downward trend. Before 1885, when the hospitals were maintained by voluntary contributions and Government subsidy, one-ninth of the total expenditure was met by voluntary contributions; at present this proportion is only one-twentieth.

Among the special reports in the volume reference may be made to that on the maternity hospitals, from which it appears that in the four St. Helen's hospitals, respectively at Christchurch, Auckland, Wellington, and Dunedin, as many as 4303 births took place—about one-seventh of the total births during the year; and to that of the laboratory of medical pathology and vaccine station at Wellington, in which it is clear that much good and varied work is being done.

The examinations of the Royal Sanitary Institute in sanitary science were passed by 14 candidates, and those for inspector of nuisances by 39 candidates, during the year. Mr. Valintine points out that any proposals to conduct similar examinations departmentally are outweighed by the consideration that the certificates obtainable from the Royal Sanitary Institute have a standard value which is recognised throughout the British Empire.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8957 births and 5256 deaths were registered during the week ended Saturday, Feb. 28th. The annual rate of mortality in these towns, which had steadily declined from 18·4 to 15·0 per 1000 in the four preceding weeks, slightly rose to 15·1 per 1000 in the week under notic [illegible] mea [illegible] 16 6 [illegible] seve [illegible] Eal [illegible] East [illegible] 23 9 in Wigan, 24·2 in Burnley, and 28 0 in Barnsley.

The 5256 deaths from all causes were 53 in excess of the number in the previous [illegible] were [illegible] and [illegible] ths, [illegible] scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean [illegible] last week was equal t [illegible] in the two precedi [illegible] to 115 last week, and [illegible] es of 1·1 in Sheffield, 1·2 [illegible] ton.), 1·4 in Smethwick, [illegible] Hartlepool, and 1·7 in Swansea. The deaths referred to measles, which had been 64, 89, and 115 in the three preceding weeks, declined to 101 last week; the highest death-rates from this disease were 1·6 in Leicester, 1·9 in Rhondda, 2·2 in Cardiff, 2·9 in Barnsley, and 5·7 in Burnley. The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 66, 68, and 70 in t [illegible] 83 last week; of t [illegible] Liverpool, 6 in [illegible] Birmingham, an [illegible] to diphtheria, which had been 70, 64, and 52 in the three preceding weeks, rose to 72 last week, and included 17 in London and its suburban districts, 9 in Birmingham, 4 in Liverpool, 3 in Southampton, and 3 in Manchester. The deaths referred to scarlet fever, which had been 38, 37, and 33 in the three preceding weeks, were 34 last week, of which 7 were registered in Birmingham, 4 in Manchester, 3 in London, 3 in Oldham, and 2 in South Shields. The fatal cases of enteric fever, which had been 21, 14, and 17 in the three preceding weeks, declined to 8 last week, and included 2 in Leeds.

The number of scarlet fever pat [illegible] the Metropolitan Asylums and the [illegible] which had declined from 3599 to [illegible] weeks, had [illegible] cases were [illegible] against 559, 426, and 351 in [illegible] These hospitals also contain [illegible] of diphtheria, 315 of whooping [illegible] enteric fever, and 1 of small-p [illegible] causes in London were 8 fewer than the number in the previous week, and were equal to an annual death-rate of 14·1 per 1000. The deaths referred to diseases of the respiratory system, which had declined from 425 to 245 in the four preceding weeks, were 243 last week, and were 144 below the number recorded in the corresponding week of last year.

Of the 5256 deaths from all causes in the 97 towns, 156 [illegible] of violence, and 350 were [illegible] The causes of 50, or 1·0 [illegible] week 12 were [illegible] London, 4 in [illegible] Gloucester.

HEALTH OF SCOTCH TOWNS.

In [illegible] popula-tion [illegible] year, 1278 [illegible] the week [illegible] ite of mort [illegible] from 20 9 [illegible] ose to 17·5 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 18·9, against a corresponding rate of 16·8 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 6·3 in Falkirk, 7·7 in Perth, and 11·3 in Motherwell, to 19·2 in Dundee, 20·9 in Edinburgh, and 21·1 in Clydebank.

The 770 deaths from all causes were 43 in excess of the number in the previous week, and included 98 which were referred to the principal epidemi [illegible] rising from 68 to 82 in the three [illegible] 98 deaths, 48 resulted from measl [illegible] from whooping cough, 13 from [illegible] and 11 from diphtheria, but not one from enteric fever or from small-pox. *These 98 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·2, against* 1·2 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 34, 41, and 42 in the three preceding weeks, further rose to 48 last week, of which 28 occurred in Glasgow, 9 in Edinburgh, 4 in Ayr, and 3 in Leith. The deaths referred to scarlet fever, which had been 6, 7, and 6 in the three preceding weeks, rose to 13 last week, and included 4 in Glasgow, 3 in Edinburgh, 2 in Dundee, and 2 in Kirkcaldy The fatal cases of whooping-cough, which had declined from 7 to 3 in the four preceding weeks, rose to 13 last week; 7 deaths were recorded in Glasgow, 3 in Coatbridge, and 2 in Paisley. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 7, 8, and 16 in the three preceding weeks, fell to 13 last week, of which 7 were registered in Glasgow. The fatal cases of diphtheria, which had been 15, 12, and 14 in the three preceding weeks, declined to 11 last week, and comprised 4 in Glasgow, 3 in Aberdeen, 2 in Edinburgh, and 2 in Dundee

The deaths referred to diseases of the respiratory system, which had decreased from 230 to 143 in the six preceding weeks, further fell to 116 in the week under notice; 15 deaths were attributed to various forms of violence, against numbers declining from 36 to 22 in the four preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 618 births and 480 deaths were registered during the week ended Saturday, Feb. 28th. The annual rate of mortality in these towns, which had been 21·9, 18 9, and 19 1 per 1000 in the three preceding weeks, further rose to 20 8 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean [illegible] eraged 21·9 per [illegible] responding rate [illegible] wns it was equal [illegible] week was equal [illegible] 17·5 in Glasgow), [illegible] onderry, 29 8 in [illegible] the 21 smaller [illegible] in excess of the [illegible] and included 35 which were [illegible] 2·2 per 1000. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 7, 8, and 10 in the three preceding weeks, were 9 last week, of which 4 occurred in Belfast, 2 in Dublin, and 2 in Cork. The deaths referred to measles, which had been 8, 5, and 3 in the three preceding weeks, rose to 8 last week, and comprised 7 in Dublin and 1 in Lisburn. The fatal cases of scarlet fever, which had been 10, 9, and 3 in the three preceding weeks, rose to 8 last week, of which 6 were registered in Belfast and 2 in Dublin. The 6 deaths [illegible] of which 4 occurred in Belfast, [illegible] earlier weeks of the quarter. [illegible] ere recorded in Dublin, and [illegible] ver in Dublin and Clonmel [illegible] exceed 1·0 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Robert Howard Nicholson has been placed on the Retired List at his own request (dated March 1st, 1914).

The following appointments have been notified:—Fleet-Surgeons: E. R. Grazebrook to the *Neptune* on transfer of flag; and W. J. Colborne to the *Iron Duke* and for general staff duties on commissioning. Staff-Surgeons: E. A. G. Wilkinson to the *Iron Duke* on commissioning; G. Nunn to the *Neptune* on transfer of flag; J. Whelan to the *Exmouth;* P. T. Sutcliffe to the *Cyclops;* and R. F. MacMahon to the *Hindustan.*

ARMY MEDICAL SERVICE.

Colonel Edward Butt, from Half-pay List, is placed on retired pay (dated March 4th, 1914).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated March 1st, 1914):—Brevet Major Arthur B. Smallman, Wentworth F. Tyndale, C.M.G., William F. Ellis, Ralph B. Ainsworth, Charles A. J. A. Balck, Dudley S. Skelton, Philip G. Easton, and Richard Rutherford.

Colonel J. Maher has taken up duty as Assistant Director of Medical Services at Gibraltar.

Lieutenant-Colonel E. Eckersley has been selected for the increased rate of pay under Article 358 of the Royal Warrant for Promotion. Lieutenant-Colonel C. W. H. Whitehouse has been appointed to hold charge of the Military Hospital at Hilsea. Lieutenant-Colonel J. F. Donegan has embarked on the transport s.s. *Plassy* for a tour of service in India. An exchange of duty in India has been effected between Lieutenant-Colonel H. E. Winter to the Sixth (Poona) Division, vice Lieutenant-Colonel G. A. T. Bray to the Home Establishment. Lieutenant-Colonel D. M. O'Callaghan has been transferred from Hilsea to Dover and appointed to hold charge of the Military Hospital, vice Lieutenant-Colonel F. R. Newland. Lieutenant-Colonel G. G. Adams has arrived home on leave of absence from the Military Hospital at Secunderabad Cantonment. Lieutenant-Colonel H. C. Thurston has been restored to the Establishment, vice Lieutenant-Colonel A. R. Aldridge, retired. Lieutenant-Colonel T. B. Winter has relinquished charge of the Military Hospital at Colchester. Lieutenant-Colonel A. L. E. Bate has joined the Woolwich District.

Major S. L. Cummins has been appointed Professor of Pathology and Bacteriology at the Royal Army Medical College, vice Brevet Colonel and Lieutenant-Colonel Sir William Leishman. Major E. P. Hewitt has been placed temporarily on the Half-pay List on account of ill-health. Major J. G. Foster has arrived home on leave of absence from the Military Hospital at Ahmednagar Cantonment. Major C. W. Reilly has taken over charge of the Military Hospital at Bodmin. Major J. Crawford Kennedy has embarked for a tour of service with the Eighth (Lucknow) Division of the Northern Army in India. Major J. H. R. Bond has arrived home on general leave of absence from the Military Hospital at Naini Tal. Major W. A. Ward has been appinted to the Southern Command. Major S. de C. O'Grady has been appointed to the Aldershot Command for duty. Major N. H. Ross has been appointed Specialist in the Prevention of Disease and placed in charge of the Research Bacteriological Laboratory at Brigade Headquarters, Fyzabad Cantonment. Major H. F. Shea has been appointed Specialist in Operative Surgery at Lahore. Major N. E. J. Harding has taken up duty as Medical Officer at the Tower of London. Major T. B. Unwin has arrived home on general leave of absence from the Military Hospital at Mount Auriol, Sierra Leone Protectorate. Major W. R. Blackwell has been appointed for temporary duty at the Medical Division of the War Office on arrival home from Lucknow.

Captain H. W. Russell has been appointed to the Military Hospital at Ambala Cantonment. Captain C. R. Millar has taken up duty in the Irish Command. Captain A. W. Byrne has taken up duty as Sanitary Specialist to the Third (Lahore) Division. Captain D. de C. O'Grady has been appointed to the Eastern Command. Captain J. R. Foster has taken up duty in the Irish Command on transfer home from India. Captain G. G. Collet has been appointed Specialist in Dermatology to the Seventh (Meerut) Division. Captain A. H. Heslop has been transferred from the Indian to the Home Establishment. Captain T. S. Coates has taken up duty in India. Captain H. L. Howell has been transferred from the Military Hospital at Ahmednagar Cantonment to Kirkee. Captain T. W. Browne has arrived home for duty from the Military Hospital at Jhansi. Captain W. A. Spong, staff-surgeon at Karachi Cantonment, has been granted six months' general leave of absence home from India. Captain C. W. Bowle has been appointed to the Irish Command. Captain J. J. O'Keefe has arrived home for duty from the Military Hospital at Naini Tal, tour expired. Captain G. F. Dawson has been transferred from the Military Hospital at Chakrata to Bareilly Cantonment. Captain F. Worthington has arrived home for duty from Ceylon. Captain A. G. Wells has been transferred from the Military Hospital at Kasauli Cantonment to Ambala. Captain T. H. Scott has arrived home for duty from Ferozepore Cantonment, tour expired. Captain J. Mackenzie has relinquished duty at Pirbright and embarked for India. Captain B. A. Odlum has been seconded for service under the Colonial Office. Captain W. H. S. Burney has been transferred from the Military Hospital at Campbellpore to Ferozepore Cantonment. Captain E. M. Middleton has arrived home for duty from Rawal Pindi, tour expired. Captain E. C. Phelan has been appointed for duty on board the transport s.s. *Plassy*, leaving Bombay for Southampton on March 12th with invalids. Captain J. R. Lloyd has been transferred from the Military Hospital at Jubbulpore Cantonment to the Aden Brigade. Captain H. J. Crossley has relinquished duty at Richmond (Yorks) and embarked for India. Captain D. M. Corbett has been appointed for duty on board the transport s.s. *Rohilla*, leaving Karachi on March 19th with time-expired troops for Southampton Docks. Captain F. J. Stuart has been transferred from the Military Hospital at Chakrata to Meerut Cantonment. Captain A. W. Howlett has arrived home for duty from Bareilly Cantonment, tour expired. Captain N. Low has been selected for appointment as Specialist Sanitary Officer to the Eastern Command, North of Thames area, vice Major P. S. Lelean, appointed Assistant Professor of Hygiene at the Royal Army Medical College.
